BD Chaurasia’s Human Anatomy

Regional and Applied Dissection and Clinical

As per Medical Council of India: Competency based Undergraduate Curriculum for the Indian Medical Graduate, 2018
Dr BD Chaurasia (1937–1985)

was Reader in Anatomy at GR Medical College, Gwalior.
He received his MBBS in 1960, MS in 1965 and PhD in 1975.
He was elected fellow of National Academy of Medical Sciences (India) in 1982.
He was a member of the Advisory Board of the Acta Anatomica since 1981,
member of the editorial board of Bionature, and in addition
member of a number of scientific societies.
He had a large number of research papers to his credit.
Regional and Applied Dissection and Clinical

As per Medical Council of India: Competency based Undergraduate Curriculum for the Indian Medical Graduate, 2018
to

my teacher
Shri Uma Shankar Nagayach

— BD Chaurasia
This human anatomy is not systemic but regional
Oh yes, it is theoretical as well as practical
Besides the gross features, it is chiefly clinical
Clinical too is very much diagrammatical.

Lots of tables for the muscles are provided
Even methods for testing are incorporated
Improved colour illustrations are added
So that right half of brain gets stimulated

Tables for muscles acting on joints are given
Tables for branches of nerves and arteries are given
Hope these volumes turn highly useful
Editors’ hardwork under Almighty’s guidance prove fruitful
Preface to the Eighth Edition

The Seventh edition was published in 2016. The newly added fourth volume on brain–neuroanatomy received an excellent response from the students and the teachers alike.

The Eighth edition also brings new changes, surprises, modifications and highlights. It has been designed as per MCI BoG Syllabus 2018 featuring the text and headings following the “Competency based Undergraduate Curriculum for the Indian Medical Graduate 2018”, prescribed by Medical Council of India.

Many readers and teachers gave a feedback of retaining the cranial nerves in Volume 3, therefore, a brief description of all the cranial nerves has been given in the appropriate chapters.

Text, along with the illustrations, has been thoroughly updated. Many new diagrams have been added and the earlier ones modified for easy comprehension. Some selected diagrams from the very first edition have been adapted, recreated and incorporated in these volumes.

Quite a few radiographs and MRIs have been added to keep up with the new developments. Extensive editing, especially developmental editing, has been done.

Extensive research has decoded the molecular control of development of organ tissues of the body. An attempt has been made to introduce molecular regulation of development of some organs in the book. Hope the teachers would explain them further for better understanding of the interesting aspect of embryology. It is known that many of the adult diseases have a foetal origin.

The text provides essential and relevant information to all the students. For still better and detailed learning, some selected bibliographic references have been given for inquisitive students.

The cadaveric dissection is the ‘real/actual anatomy’. Since some of these were introduced in the seventh edition, more diagrams of dissection have been added for the undergraduate students, so they will not miss carrying out the dissections (due to lack of cadavers).

For testing the knowledge acquired after understanding the topic, Viva Voce questions have been added. These would prove useful in theory, practical, viva voce and grand viva voce examinations. Since so much has been added to these holistic volumes, the size would surely increase, though making the text as compatible with the modern literature as is possible. Most of it is visual and anatomy as a basic component of medicine remains a subject of practical exploration.

We have satisfactorily modified text to suit requirements of horizontal and vertical integrations of anatomy with other preclinical, paraclinical and clinical subjects as per BoG NMC (erstwhile MCI) guidelines.

Happy Reading.

Krishna Garg
Chief Editor
email: dr.krishnagarg@gmail.com
The necessity of having a simple, systematized and complete book on anatomy has long been felt. The urgency for such a book has become all the more acute due to the shorter time now available for teaching anatomy, and also to the falling standards of English language in the majority of our students in India. The national symposium on ‘Anatomy in Medical Education’ held at Delhi in 1978 was a call to change the existing system of teaching the unnecessary minute details to the undergraduate students.

This attempt has been made with an object to meet the requirements of a common medical student. The text has been arranged in small classified parts to make it easier for the students to remember and recall it at will. It is adequately illustrated with simple line diagrams which can be reproduced without any difficulty, and which also help in understanding and memorizing the anatomical facts that appear to defy memory of a common student. The monotony of describing the individual muscles separately, one after the other, has been minimised by writing them out in tabular form, which makes the subject interesting for a lasting memory. The relevant radiological and surface anatomy have been treated in separate chapters. A sincere attempt has been made to deal, wherever required, the clinical applications of the subject. The entire approach is such as to attract and inspire the students for a deeper dive in the subject of anatomy.

The book has been intentionally split in three parts for convenience of handling. This also makes a provision for those who cannot afford to have the whole book at a time.

It is quite possible that there are errors of omission and commission in this mostly single-handed attempt. I would be grateful to the readers for their suggestions to improve the book from all angles.

I am very grateful to my teachers and the authors of numerous publications, whose knowledge has been freely utilised in the preparation of this book. I am equally grateful to my professor and colleagues for their encouragement and valuable help. My special thanks are due to my students who made me feel their difficulties, which was a great incentive for writing this book. I have derived maximum inspiration from Prof. Inderbir Singh (Rohtak), and learned the decency of work from Shri SC Gupta (Jiwaji University, Gwalior).

I am deeply indebted to Shri KM Singhal (National Book House, Gwalior) and Mr SK Jain (CBS Publishers & Distributors, Delhi), who have taken unusual pains to get the book printed in its present form. For giving it the desired get-up, Mr VK Jain and Raj Kamal Electric Press are gratefully acknowledged. The cover page was designed by Mr Vasant Paranje, the artist and photographer of our college; my sincere thanks are due to him. I acknowledge with affection the domestic assistance of Munne Miyan and the untiring company of my Rani, particularly during the odd hours of this work.

BD Chaurasia
Foremost acknowledgement is the extreme gratefulness to almighty for ‘All Time Guidance’ during the preparation of the Eighth edition. All the editors are sincerely obliged to Dr VG Sawant, Dr NA Faruqi, Dr Gayatri Rath, Dr Ritesh Shah, Dr SN Kazi, Dr N Vasudeva, Dr Sabita Mishra, Dr Mangla Kohli, Dr Satyam Khare, Dr Nisha Kaul, Dr Azmi Mohsin, Dr Medha Joshi and Dr Surbhi Garg for making this edition noteworthy.

The suggestions provided by Dr DC Naik, Dr Ved Prakash, Dr Mohini Kaul, Dr Indira Bahl, Dr SH Singh, Dr Rewa Choudhary, Dr Shipra Paul, Dr Anita Tuli, Dr Shashi Raheja, Dr Sneh Aggarwal, Dr RK Suri, Dr Vadana Mehta, Dr Veena Bhardwok, Dr Mahindra Nagar, Dr Renu Chauhan, Dr Sunita Kalra, Dr RK Ashoka, Dr Vivek Parashar, Mr Buddhadev Ghosh, Mr Kaushik Saha, Dr Dinesh Kumar, Dr AK Garg, Dr Archana Sharma, Dr Shipli Jain, Dr Poonam Kharab, Dr Mahindra K Anand, Dr Daisy Sahni, Dr Kiran Vasudeva, Dr Rashmi Bhardwaj, Dr Arqam Miraj, Dr Joseph, Dr Harsh Plumal, Dr Yogesh Sontakke, HA Buch, Umang Sharma, Dr Nikha Bhardwaj and many friends and colleagues are gratefully acknowledged. They have been providing help and guidance to sustain the responsibility of upkeeping the standard of these volumes.

Videos of bones and soft parts of human body prepared at Kathmandu University School of Medical Sciences were added in the CDs along with the Frequently Asked Questions. I am grateful to Dr R Koju, CEO of KUSMS and Dhalikhe Hospital, for his generosity. This material is now available at our mobile App CBSiCentral.

The moral support of the family members is appreciated. The members are Dr DP Garg, Mr Satya Prakash Gupta, Mr Ramesh Gupta, Dr Suvira Gupta, Dr JP Gupta, Mr Manoj, Ms Rekha, Master Shikhar, Mr Sanjay, Mrs Meenakshi, Kriti, Kanika, Dr Manish, Dr Shipra, Meera and Raghav. Dr Shipra Mittal and Dr Sushant Rit, Mr Rishabh Malhotra have been encouraging and inspiring us in the preparation of the volumes.

The magnanimity shown by Mr SK Jain (Chairman) and Mr Varun Jain (Director), CBS Publishers & Distributors Pvt Ltd, has been ideal and always forthcoming.

The unquestionable support of Mr YN Arjuna (Senior Vice President—Publishing, Editorial and Publicity) and his entire team comprising Ms Ritu Chawla (GM—Production), Mr Sanjay Chauhan (graphic artist) with his unflagging efforts on drawings, Ms Jyoti Kaur (DTP operator), for excellent formatting, Mr Surendra Jha (copyeditor), Mr Neeraj Sharma (copyeditor), Ms Meena Bhaskar (typing) and Mr Neeraj Prasad (graphic artist) for layout and cover designing have done excellent work to bring out the eighth edition. I am really obliged to all of them.

Krishna Garg
Chief Editor
Handle me with little love and care
As I had missed it in my life affair
Was too poor for cremation or burial
That is why I am lying in dissection hall

You dissect me, cut me, section me
But your learning anatomy should be precise
Worry not, you would not be taken to court
As I am happy to be with the bright lot

Couldn’t dream of a fridge for cold water
Now my body parts are kept in refrigerator
Young students sit around me with friends
A few dissect, rest talk, about food, family and movies
How I enjoy the dissection periods
Don’t you? Unless you are interrogated by a teacher

When my parts are buried post-dissection
Bones are taken out for the skeleton
Skeleton is the crown glory of the museum
Now I am being looked up by great enthusiasm

If not as skeletons as loose bones
I am in their bags and in their hostel rooms
At times, I am on their beds as well
Oh, what a promotion to heaven from hell

I won’t leave you, even if you pass anatomy
Would follow you in forensic medicine and pathology
Would be with you even in clinical teaching
Medicine line is one where dead teach the living

One humble request I’d make
Be sympathetic to persons with disease
Don’t panic, you’ll have enough money
And I bet, you’d be singularly happy

Thus spoke the cadaver

## Preface to the Eighth Edition
Preface to the First Edition (excerpts)
Index of Competencies

### Section 1  UPPER LIMB

1. **Introduction**  
   - Parts of the Upper Limb  3  
   - Evolution of Upper Limbs  4  
   - Study of Anatomy  5  
   - Frequently Asked Questions  5  

2. **Bones**  
   - Introduction  6  
   - Clavicle  6  
   - Ossification  8  
   - Clinical Anatomy  8  
   - Scapula  8  
   - Ossification  12  
   - Clinical Anatomy  13  
   - Humerus  13  
   - Ossification  16  
   - Clinical Anatomy  17  
   - Radius  18  
   - Ossification  21  
   - Clinical Anatomy  21  
   - Ulna  22  
   - Ossification  23  
   - Clinical Anatomy  23  
   - Ossification of Humerus, Radius and Ulna  24  
   - Importance of Capsular Attachments and Epiphyseal Lines  24  
   - Clinical Anatomy  25  
   - Carpal Bones  25  
   - Ossification  27  
   - Clinical Anatomy  27  
   - Metacarpal Bones  27  
   - Ossification  31  
   - Clinical Anatomy  31  
   - Phalanges  32  
   - Ossification  32  

   - Clinical Anatomy  33  
   - Sesamoid Bones  33  
   - Mnemonics  33  
   - Facts to Remember  33  
   - Clinicoanatomical Problem  33  
   - Further Reading  34  
   - Frequently Asked Questions  34  
   - Multiple Choice Questions  34  
   - Viva Voce  34, 35  

3. **Pectoral Region**  
   - Introduction  36  
   - Surface Landmarks  36  
   - Dissection  37  
   - Superficial Fascia  37  
   - Breast  38  
   - Lymphatic Drainage  41  
   - Clinical Anatomy  43  
   - Deep Fascia  45  
   - Muscles of the Pectoral Region  45  
   - Serratus Anterior  48  
   - Dissection  49  
   - Mnemonics  49  
   - Facts to Remember  49  
   - Clinicoanatomical Problem  49  
   - Further Reading  49  
   - Frequently Asked Questions  50  
   - Multiple Choice Questions  50  
   - Viva Voce  50  

4. **Axilla**  
   - Introduction  51  
   - Dissection  51  
   - Boundaries  51  
   - Contents of Axilla  53
Clinical Anatomy 54
Axillary Artery 54
Relations of Axillary Artery 54
Clinical Anatomy 58
Axillary Vein 58
Axillary Lymph Nodes 58
Clinical Anatomy 59
Spinal Nerve 59
Brachial Plexus 59

Ethical Aspects of Cadaveric Dissection

The cadaver, the dead body, that we dissect, plays an important role in the teaching of anatomy to medical students. The cadaver and the bones become an important part of our life as medical students as some academics have even referred to the cadaver as the ‘first teacher’ in the medical school.

We must pay due respect to the cadavers and bones kept in the dissection hall or museum. In some medical schools it is mandatory to take an ‘oath’ before beginning the cadaveric dissection which aims to uphold the dignity of the mortal remains of the departed soul while other medical schools help the student to undertake dissection in a proper manner and empathise with the families of the donor. During the course of dissection the student is constantly reminded of the sanctity of the body he/she is studying so that the noble donation of someone’s body is used only as a means of gaining scientific knowledge/progress. Each and every dissected part afterwards is disposed or cremated with full dignity.

Honour of the donor and his/her family is the prime responsibility of the health professional. ‘The dead teach the living’, and the living pledge to use this knowledge for the upliftment of humankind.

Three-dimensional models and computer simulations cannot replace the tactile appreciation achieved by cadaveric dissection and we should always be grateful to those who have donated their bodies and strive to respect them. We have the privilege to study the human being through a body of a fellow human and have to be humble and carry forward the legacy of nobility and selflessness in our careers.

The fore- and hindlimbs were evolved basically for bearing the weight of the body and for locomotion as is seen in quadrupeds, e.g. cows or dogs. The two pairs of limbs are, therefore, built on the same basic principle.

Each limb is made up of a basal segment or girdle, and a free part divided into proximal, middle and distal segments. The girdle attaches the limb to the axial skeleton. The distal segment carries five digits. Table 1.1 shows homologous parts of upper and lower limbs.

However, with the evolution of the erect posture in man, the function of weight-bearing was taken over by the lower limbs. Thus the upper limbs, especially the hands, became free and gradually evolved into organs having great manipulative skills.

This has become possible because of a wide range of mobility at the shoulder. The whole upper limb works as a jointed lever. The human hand is a grasping tool. It is exquisitely adaptable to perform various complex functions under the control of a large area of the brain. The unique position of man as a master mechanic of the animal world is because of the skilled movements of his hands.

### PARTS OF THE UPPER LIMB

It has been seen that the upper limb is made up of four parts: (1) Shoulder region; (2) arm or brachium; (3) forearm or antebrachium; and (4) hand or manus. Further subdivisions of these parts are given in Table 1.2 and Fig. 1.1.

**Fig. 1.1**: Parts and 32 bones of the upper limb
1 The shoulder region includes:
   a. The pectoral or breast region on the front of the chest;
   b. The axilla or armpit; and
   c. The scapular region on the back comprising parts around the scapula.

   The bones of the shoulder girdle are the clavicle and the scapula.

   Of these, only the clavicle articulates with the axial skeleton at the sternoclavicular joint. The scapula is mobile and is held in position by muscles. The clavicle and scapula articulate with each other at the acromioclavicular joint.

2 The arm (upper arm or brachium) extends from the shoulder to the elbow (cubitus). The bone of the arm is the humerus. Its upper end meets the scapula and forms the shoulder joint. The shoulder joint permits movements of the arm.

3 The forearm (antebrachium) extends from the elbow to the wrist. The bones of the forearm are the radius and the ulna. At their upper ends, they meet the lower end of the humerus to form the elbow joint. Their lower ends meet the carpal bones to form the wrist joint. The radius and ulna meet each other at the radioulnar joints.

   The elbow joint permits movements of the forearm, namely flexion and extension. The radioulnar joints permit rotatory movements of the forearm called pronation and supination. In a mid-flexed elbow, the palm faces upwards in supination and downwards in pronation. During the movement of pronation, the radius rotates around the ulna (see Fig. 10.23).

4 The hand (manus) includes:
   a. The wrist or carpus, supported by 8 carpal bones arranged in two rows.
   b. The hand proper or metacarpus, supported by 5 metacarpal bones.
   c. Five digits (thumb and four fingers). Each finger is supported by three phalanges, but the thumb has only 2 phalanges (there being 14 phalanges in all).

   The carpal bones form the wrist joint with the radius, intercarpal joints with one another, and carpometacarpal joints with the metacarpals.

   The phalanges form metacarpophalangeal joints with the metacarpals and interphalangeal joints with one another.

   Movements of the hand are permitted chiefly at the wrist joint. The thumb moves at the first carpometacarpal joint; where an exclusive movement of opposition besides the other usual movements is permitted. Each of the second to fifth digits moves at metacarpophalangeal, proximal and distal interphalangeal joints. Figure 1.2 and Flowchart 1.1 show the lines of force transmission.

**EVOLUTION OF UPPER LIMBS**

The forelimbs have evolved from the pectoral fins of fishes. In tetrapods (terrestrial/land vertebrates), all the four limbs are used for supporting body weight, and for locomotion. In arboreal (tree-dwelling) human ancestors, the forelimbs have been set free from their weight-bearing function. The forelimbs, thus ‘emancipated’,
acquired a wide range of mobility and were used for prehension or grasping, feeling, picking, holding, sorting, breaking, fighting, etc. These functions became possible only after necessary structural modifications:

a. Appearance of joints permitting rotatory movements of the forearm (described as supination and pronation), as a result of which food could be picked up and taken to the mouth.

b. Addition of the clavicle, which has evolved with the function of prehension.

c. Rotation of the thumb through 90°, so that it can be opposed to other digits for grasping.

d. Appropriate changes for free mobility of the fingers and hand.

The primitive pentadactyl limb of amphibians, terminating in five digits, has persisted through evolution and is seen in man. In some other species, however, the limbs were altogether lost, as in snakes; while in others the digits were reduced in number as in ungulates. The habit of brachiation, i.e. suspending the body by the arms, in anthropoid apes resulted in disproportionate lengthening of the forearms, and also in elongation of the palm and fingers.

**STUDY OF ANATOMY**

Before studying the anatomy of any region, it is usual to begin by learning general features of the skin, the superficial fascia and its contents, the deep fascia, the muscles, joints, blood vessels and nerves. All these are provided in *BD Chaurasia’s Handbook of General Anatomy*, 6th edition. This is followed by the study of the muscles of the region, and finally, the blood vessels and nerves. These descriptions should be read only after the part has been dissected with the help of the steps of dissection provided in the book.

Before undertaking the study of any part of the body, it is essential for the students to acquire some knowledge of the bones of the region. It is for this reason that a chapter on bones (osteology) is given at the beginning of each section. While reading the chapter, the students should palpate the various parts of bones on themselves. The next chapter must be studied with the help of loose human bones.

**Frequently Asked Questions**

1. Make a flowchart to show lines of force transmission in upper limb.
2. Tabulate the homologous parts of upper and lower limbs.
3. Enumerate:
   a. Subdivisions of shoulder region
   b. Joints related to the forearm
   c. Name of carpal bones in order
   d. Joints of the hand
Competency achievement: The student should be able to:

AN 8.1 Identify the given bone, its side, important features and keep it in anatomical position.¹

AN 8.2 Identify and describe joints formed by the given bone.²

Competency achievement: The student should be able to:

AN 8.3 Enumerate peculiarities of clavicle.³

INTRODUCTION

Out of 206 total bones in man, the upper limbs contain as many as 64 bones. Each side consists of 32 bones, the distribution of which is shown in Table 1.2 and Fig. 1.1 (see Chapter 1). Since bones of the two upper limbs are similar, one needs to learn only 32 bones out of a total 64 bones. This applies to soft parts as well. One learns only one upper limb, the other upper limb gets learnt on its own. This is true for the whole body except parts of abdomen. Actually, one needs to master only 50% of the body and other 50% gets mastered itself. The individual bones of the upper limb will be described one by one. Their features and attachments should be read with the bones before undertaking the dissection of the part concerned. The paragraphs on attachments should be revised when the dissection of a particular region has been completed.

Competency achievement: The student should be able to:

AN 8.3 Enumerate peculiarities of clavicle.³

CLAVICLE

The clavicle (Latin a small key) is a long bone. It supports the shoulder so that the arm can swing clearly away from the trunk. The clavicle transmits the weight of the limb to the sternum. The bone has a curved part called the shaft, and two ends, lateral and medial.

Side Determination

The side to which a clavicle belongs can be determined from the following characters.

   1. The lateral end is flat, and the medial end is large and quadrilateral.
   2. The shaft is slightly curved, so that it is convex forwards in its medial two-thirds, and concave forwards in its lateral one-third.
   3. The inferior surface is grooved longitudinally in its middle one-third.

The clavicle (Latin a small key) is a long bone. It supports the shoulder so that the arm can swing clearly away from the trunk. The clavicle transmits the weight of the limb to the sternum. The bone has a curved part called the shaft, and two ends, lateral and medial.

Features

Shaft

The shaft (Figs 2.1a and b) is divisible into the lateral one-third and the medial two-thirds.

The lateral one-third of the shaft is flattened from above downwards. It has two borders—anterior and posterior. The anterior border is concave forwards. The posterior border is convex backwards. This part of the bone has two surfaces—superior and inferior. The superior surface is subcutaneous and the inferior surface presents an elevation called the conoid (Greek cone) tubercle and a ridge called the trapezoid ridge.

The medial two-thirds of the shaft is rounded and is said to have four surfaces. The anterior surface is convex forwards. The posterior surface is smooth. The superior surface is rough in its medial part.
**Bones**

**Upper Limb**

1. The lateral or acromial (Greek *peak of shoulder*) end is flattened from above downwards. It bears a facet that articulates with the acromion process of the scapula to form the acromioclavicular joint.

2. The medial or sternal end is quadrangular and articulates with the clavicular notch of the manubrium sterni to form the sternoclavicular joint. The articular surface extends to the inferior aspect, for articulation with the first costal cartilage.

**Competency achievement:** The student should be able to:

AN 8.4 Demonstrate important muscle attachments on the given bone.

**Attachments**

1. *At the lateral end*, the margin of the articular surface for its acromioclavicular joint gives attachment to the joint capsule.

2. *At the medial end*, the margin of the articular surface for the sternum gives attachment to:
   a. Fibrous capsule of sternoclavicular joint all around (Figs 2.2a and b).
   b. Articular disc posterolaterally.
   c. Interclavicular ligament superiorly.

---

**Figs 2.1a and b:** General features of right clavicle: (a) Superior aspect, and (b) inferior aspect

**Figs 2.2a and b:** Attachments of right clavicle: (a) Superior aspect, and (b) inferior aspect
3 **Lateral one-third of shaft**
   a. The anterior border gives origin to the *deltoid* muscle (Fig. 2.2a).
   b. The posterior border provides insertion to the *trapezius* muscle.
   c. The conoid tubercle and trapezoid ridge give attachment to the conoid and trapezoid parts of the *coracoclavicular ligament* (Fig. 2.2b).

4 **Medial two-thirds of the shaft**
   a. Most of the anterior surface gives origin to the *pectoralis major* (Figs 2.2a and b).
   b. Half of the rough superior surface gives origin to the *clavicular head of the sternocleidomastoid* (Fig. 2.2a).
   c. The oval impression on the inferior surface at the medial end gives attachment to the *costoclavicular ligament* (Fig. 2.2b).
   d. The subclavian groove gives insertion to the *subclavius muscle*. The margins of the groove give attachment to the *clavipectoral fascia*.
   e. The posterior surface close to medial end gives origin to the *sternohyoid muscle*.
   f. The *subclavian vessels* and *divisions of trunks of brachial plexus* pass towards the axilla lying between the inferior surface of the clavicle and upper surface of first rib. Subclavius muscle acts as a cushion.

   The nutrient foramen transmits a branch of the suprascapular artery.

**OSSIFICATION**

- The clavicle is the first bone in the body to ossify (Fig. 2.3). Except for its medial end, it ossifies in membrane. It ossifies from two primary centres and one secondary centre.
- The two primary centres appear in the shaft between the fifth and sixth weeks of intrauterine life, and fuse about the 45th day.
- The secondary centre for the medial end appears during 15–17 years, and fuses with the shaft during 21–22 years. Occasionally, there may be a secondary centre for the acromial end.

**CLINICAL ANATOMY**

- The clavicle is commonly fractured by falling on the outstretched hand (indirect violence). The most common site of fracture is the junction between the two curvatures of the bone, which is the weakest point. The lateral fragment is displaced downwards by the weight of the limb as trapezius muscle alone is unable to support the weight of upper limb (Fig. 2.4).
- The clavicles may be congenitally absent, or imperfectly developed in a disease called *cleidocranial dysostosis*. In this condition, the shoulders droop, and can be approximated anteriorly in front of the chest (Figs 2.5a and b).

**SCAPULA**

The scapula (Latin *shoulder blade*) is a thin bone placed on the posterolateral aspect of the thoracic cage. The scapula has two surfaces, three borders, three angles, and three processes (Fig. 2.6).

**Side Determination**

1. The lateral or glenoid (Greek *socket*) angle is large and bears the glenoid cavity.
2. The dorsal surface is convex and is divided by the triangular spine into the supraspinous and infraspinous fossae. The costal surface is occupied by the concave subscapular fossa to fit on the convex chest wall (Figs 2.6 and 2.7).
3. The thickest lateral border runs from the glenoid cavity above to the inferior angle below.
Features

Surfaces
1. The **costal surface** or subscapular fossa is concave and is directed medially and forwards. It is marked by three longitudinal ridges. Another thick ridge adjoins the lateral border. This part of the bone is almost rod-like. It acts as a lever for the action of the **serratus anterior** in overhead abduction of the arm.
2. The **dorsal surface** gives attachment to the spine of the scapula, which divides the surface into a smaller **supraspinous fossa** and a larger **infraspinous fossa**. The two fossae are connected by the **spinoglenoid notch**, situated lateral to the root of the spine.

Borders
1. The **superior border** is shortest. Near the root of the coracoid process, it presents the **suprascapular notch**.
2. The **lateral border** is thick. At the upper end, it presents the **infraglenoid tubercle**.
3. The **medial border** is thin. It extends from the superior angle to the inferior angle.

Angles
1. The **superior angle** is covered by the trapezius.
2. The **inferior angle** is covered by the **latissimus dorsi**. It moves forwards round the chest when the arm is abducted.
3. The **lateral or glenoid angle** is broad and bears the glenoid cavity or fossa, which is directed forwards, laterally and slightly upwards (Fig. 2.7). A supra-glenoid tubercle is present above the glenoid cavity.

Processes
1. The **spine** or **spinous process** is a triangular plate of bone with three borders and two surfaces. It divides the dorsal surface of the scapula into the supraspinous and infraspinous fossae. Its posterior border is called the **crest of the spine**. The crest has upper and lower lips.
2. The **acromion** process has two borders, medial and lateral; two surfaces, superior and inferior; and a facet for the clavicle (Fig. 2.7).
3. The **coracoid** (Greek like a crow’s beak) **process** is directed forwards and slightly laterally. It is bent and finger-like. It is an atavistic type of epiphysis.

Attachments
1. The multipennate **subscapularis** muscle arises from the medial two-thirds of the subscapular fossa (Figs 2.8 and 6.4).
2. The **supraspinatus** arises from the medial two-thirds of the supraspinous fossa including the upper surface of the spine (Fig. 2.9).
3. The **infraspinatus** arises from the medial two-thirds of the infraspinous fossa, including the lower surface of the spine (Fig. 2.9).
4. The **deltoid** arises from the lower border of the crest of the spine and from the lateral border of the acromion (Fig. 2.10). The acromial fibres are **multipennate**.
5. The **trapezius** is inserted into the upper border of the crest of the spine and into the medial border of the acromion process (Fig. 2.10).
6. The **serratus anterior** is inserted along the medial border of the costal surface: One digitation from the superior angle to the root of spine, two digitations to the medial border, and five digitations to the inferior angle (Fig. 2.8).
7. The **long head of the biceps brachii** arises from the supraglenoid tubercle; and the **short head** from the lateral part of the tip of the coracoid process.
8. The **coracobrachialis** arises from the medial part of the tip of the coracoid process.
**Fig. 2.6:** General features of right scapula: Costal surface

**Fig. 2.7:** General features of right scapula: Dorsal surface
Fig. 2.8: Attachments of right scapula: Costal aspect

Fig. 2.9: Attachments of right scapula: Dorsal aspect
9 The pectoralis minor is inserted into the medial border and superior surface of the coracoid process (Fig. 2.8).
10 The long head of the triceps brachii arises from the infraglenoid tubercle.
11 The teres minor arises by two slips from the upper two-thirds of the rough strip on the dorsal surface along the lateral border (Fig. 2.9). Circumflex scapular artery lies between the two slips.
12 The teres major arises from the lower one-third of the rough strip on the dorsal aspect of the lateral border (Fig. 2.9). Latissimus dorsi arises from inferior angle.
13 The levator scapulae is inserted along the dorsal aspect of the medial border, from the superior angle up to the root of the spine (Fig. 2.9).
14 The rhomboid minor is inserted into the medial border (dorsal aspect) opposite the root of the spine (Fig. 2.9).
15 The rhomboid major is inserted into the medial border (dorsal aspect) between the root of the spine and the inferior angle.
16 The inferior belly of the omohyoid arises from the upper border near the suprascapular notch (Fig. 2.8).
17 The margin of the glenoid cavity gives attachment to the capsule of the shoulder joint and to the glenoidal labrum (Latin lip) (Fig. 2.8).
18 The margin of the facet on the medial aspect of the acromion process gives attachment to the capsule of the acromioclavicular joint (Fig. 2.10).
19 The coracoacromial ligament is attached: (a) to the lateral border of the coracoid process, and (b) to the medial side of the tip of the acromion process (Figs 2.10 and 6.7).
20 The coracohumeral ligament is attached to the root of the coracoid process (Fig. 2.10).
21 The coracoclavicular ligament is attached to the coracoid process: The trapezoid part on the superior aspect, and the conoid part near the root (Fig. 2.10).
22 The transverse ligament bridges across the suprascapular notch and converts it into a foramen which transmits the suprascapular nerve. The suprascapular vessels lie above the ligament (Fig. 2.10).
23 The spinoglenoid ligament may bridge the spinoglenoid notch. The suprascapular vessels and nerve pass deep to it (Fig. 10.3).

**OSSIFICATION**

- The scapula ossifies from one primary centre and seven secondary centres.
- The primary centre appears near the glenoid cavity during the eighth week of development.
- The first secondary centre appears in the middle of the coracoid process during the first year and fuses by the 15th year. The subcoracoid centre appears in the root of the coracoid process during the 10th year and fuses by the 16th to 18th years (Fig. 2.11).
- The other centres, including two for the acromion process, one for the lower two-thirds of the margin of the glenoid cavity, one for the medial border and one for the inferior angle, appear at puberty and fuse by the 25th year.
- The fact of practical importance is concerned with the acromion process. If the two centres appearing for acromion process fail to unite, it may be interpreted as a fracture on radiological examination. In such cases, a radiograph of the opposite acromion process will mostly reveal similar failure of union.
Paralysis of the serratus anterior causes ‘w winging’ of the scapula. The medial border of the bone becomes unduly prominent, and the arm cannot be abducted beyond 90° (Fig. 2.12).

The *scaphoid* scapula is a developmental anomaly, in which the medial border is concave.

---

### Humerus

The humerus is the bone of the arm. It is the longest bone of the upper limb. It has an upper rounded end, a lower flattened end and a shaft (Figs 2.13 and 2.14).

---

### Clinical Anatomy

- Paralysis of the serratus anterior causes ‘w winging’ of the scapula. The medial border of the bone becomes unduly prominent, and the arm cannot be abducted beyond 90° (Fig. 2.12).
- The *scaphoid* scapula is a developmental anomaly, in which the medial border is concave.

---

### Side Determination

1. The upper end is rounded to form the head. The lower end is expanded from side-to-side and flattened from before backwards.
2. The head is directed medially, upwards and backwards.
3. The lesser tubercle projects from the front of the upper end and is limited laterally by the intertubercular sulcus or bicipital groove.

### Features

**Upper End**

1. The *head* is directed medially, backwards and upwards. It articulates with the glenoid cavity of the scapula to form the shoulder joint. The head forms about one-third of a sphere and is much larger than the glenoid cavity.
2. The line separating the head from the rest of the upper end is called the *anatomical neck*.
3. The *lesser tubercle* (Latin *lump*) is an elevation on the anterior aspect of the upper end (Fig. 2.13a).
4. The *greater tubercle* is an elevation that forms the lateral part of the upper end. Its upper and posterior aspect is marked by three impressions—upper, middle and lower.
5. The *intertubercular sulcus* or bicipital groove separates the lesser tubercle medially from the anterior part of the greater tubercle. The sulcus has medial and lateral lips that represent downward prolongations of the lesser and greater tubercles.
6. The narrow line separating the upper end of the humerus from the shaft is called the *surgical neck* (Fig. 2.13b).
7. Morphological neck lies 0.5 cm below surgical neck. It shows the position of epiphyseal line (Fig. 2.13b).
Shaft
The shaft is rounded in the upper half and triangular in the lower half. It has three borders and three surfaces.

Borders
1. The upper one-third of the anterior border forms the lateral lip of the intertubercular sulcus. In its middle part, it forms the anterior margin of the deltoid tuberosity. The lower half of the anterior border is smooth and rounded.
2. The lateral border is prominent only at the lower end where it forms the lateral supracondylar ridge. In the upper part, it is barely traceable up to the posterior surface of the greater tubercle. In the middle part, it is interrupted by the radial or spiral groove (Fig. 2.13b).
3. The upper part of the medial border forms the medial lip of the intertubercular sulcus. About its middle, it presents a rough strip. It is continuous below with the medial supracondylar ridge.

Surfaces
1. The anterolateral surface lies between the anterior and lateral borders. The upper half of this surface is covered by the deltoid. A little above the middle, it is marked
by a V-shaped deltoid (Greek triangular-shaped) tuberosity. Behind the deltoid tuberosity, the radial groove runs downwards and forwards across the surface.

2 The anteromedial surface lies between the anterior and medial borders. Its upper one-third is narrow and forms the floor of the intertubercular sulcus. A nutrient foramen is seen near the medial border below its middle part (Fig. 2.13a).

3 The posterior surface lies between the medial and lateral borders. Its upper part is marked by an oblique ridge. The middle one-third is crossed by the radial groove (Fig. 2.13b).

**Lower End**

The lower end of the humerus forms the condyle which is expanded from side-to-side, and has articular and non-articular parts. The articular part includes the following:

1 The capitulum (Latin little head) is a rounded projection which articulates with the head of the radius (Fig. 2.13a).
2 The *trochlea* (Greek *pulley*) is a pulley-shaped surface. It articulates with the trochlear notch of the ulna. The medial edge of the trochlea projects down 6 mm more than the lateral edge—this results in the formation of the *carrying angle* (see Fig. 10.14).

The non-articular part includes the following.

1. The *medial epicondyle* is a prominent bony projection on the medial side of the lower end. It is subcutaneous and is easily felt on the medial side of the elbow (Fig. 2.13a).
2. The *lateral epicondyle* is smaller than the medial epicondyle. Its anterolateral part has a muscular impression.
3. The sharp lateral margin just above the lower end is called the *lateral supracondylar ridge*.
4. The *medial supracondylar ridge* is a similar ridge on the medial side.
5. The *coronoid fossa* is a depression just above the anterior aspect of the trochlea. It accommodates the coronoid process of the ulna when the elbow is flexed (Fig. 2.13a).
6. The *radial fossa* is a depression present just above the anterior aspect of the capitulum. It accommodates the head of the radius when the elbow is flexed.
7. The *olecranon* (Greek *ulna head*) fossa lies just above the posterior aspect of the trochlea. It accommodates the olecranon process of the ulna when the elbow is extended (Fig. 2.13b).

**Attachments**

1. The multipennate *subscapularis* is inserted into the lesser tubercle (Fig. 2.14a).
2. The *supraspinatus* is inserted into the uppermost impression on the greater tubercle.
3. The *infraspinatus* is inserted into the middle impression on the greater tubercle (Fig. 2.14b).
4. The *teres minor* is inserted into the lower impression on the greater tubercle (Fig. 2.14b).
5. The *pectoralis major* is inserted into the lateral lip of the intertubercular sulcus. The insertion is *bitaminar* (Figs 2.14a and b).
6. The *latissimus dorsi* is inserted into the floor of the intertubercular sulcus.
7. The *teres major* is inserted into the medial lip of the intertubercular sulcus.
8. The contents of the intertubercular sulcus are:
   a. The *tendon of the long head of the biceps brachii*, and its synovial sheath.
   b. The ascending branch of the anterior circumflex humeral artery.
9. The *deltoid* is inserted into the deltoid tuberosity (Figs 2.14a and b).
10. The *coracobrachialis* is inserted into the rough area on the middle of the medial border.

11. The *brachialis* arises from the lower halves of the anteromedial and anterolateral surfaces of the shaft. Part of the area extends onto the posterior aspect (Figs 2.14a and b).
12. The *brachioradialis* arises from the upper two-thirds of the lateral supracondylar ridge (Figs 2.14a and b).
13. The *extensor carpi radialis longus* arises from the lower one-third of the lateral supracondylar ridge.
14. The *pronator teres* (humeral head) arises from the lower one-third of the medial supracondylar ridge.
15. The superficial flexor muscles of the forearm arise by a common origin from the anterior aspect of the medial epicondyle. This is called the *common flexor origin*.
16. The superficial extensor muscles of the forearm and supinator have a common origin from the lateral epicondyle. This is called the *common extensor origin*.
17. The *anconeus* (Greek *elbow*) arises from the posterior surface of the lateral epicondyle (Fig. 2.14b).
18. Lateral head of *triceps brachii* arises from oblique ridge on the upper part of posterior surface above the radial groove, while its *medial head* arises from posterior surface below the radial groove.
19. The *capsular ligament of the shoulder joint* is attached to the anatomical neck except on the medial side where the line of attachment dips down by about 2 centimetres to include a small area of the shaft within the joint cavity. The line is interrupted at the intertubercular sulcus to provide an aperture through which the tendon of the long head of the biceps brachii leaves the joint cavity (Fig. 2.14a).
20. The *capsular ligament of the elbow joint* is attached to the lower end along a line that reaches the upper limits of the radial and coronoid fossae anteriorly; and of the olecranon fossa posteriorly; so that these fossae lie within the joint cavity. Medially, the line of attachment passes between the medial epicondyle and the trochlea. On the lateral side, it passes between the lateral epicondyle and the capitulum (Figs 2.14a and b).
21. Three nerves are directly related to the humerus and are, therefore, liable to injury—the *axillary nerve at the surgical neck*, *the radial nerve at the radial groove*, and *the ulnar nerve behind the medial epicondyle* (Fig. 2.15).

**Ossification**

- The humerus ossifies from one primary centre and seven secondary centres.
- The primary centre appears in the middle of the diaphysis during the 8th week of development.
- The upper end ossifies from three secondary centres—one for the head (first year), one for the
greater tubercle (second year), and one for the lesser tubercle (fifth year). The three centres fuse together during the sixth year to form one compound epiphysis, which fuses with the shaft during the 20th year. The epiphyseal line encircles the bone at the level of the lowest margin of the head. This is the growing end of the bone. (Remember that the nutrient foramen is always directed away from the growing end.)

- The lower end ossifies from four centres which form two epiphyses. The centres include one for the capitulum and the lateral flange of the trochlea (first year), one for the medial flange of the trochlea (9th year), and one for the lateral epicondyle (12th year). All three fuse during the 14th year to form another compound epiphysis, which fuses with the shaft at about 16 years.
- The centre for the medial epicondyle appears during 4–6 years, forms a separate epiphysis, and fuses with the shaft during the 20th year.

CLINICAL ANATOMY

- The common sites of fracture of humerus are the surgical neck, shaft and supracondylar region.
- Supracondylar fracture is common in young age. It is produced by a fall on the outstretched hand. The lower fragment is mostly displaced backwards, so that the elbow is unduly prominent, as in dislocation of the elbow joint. This fracture may cause injury to the median nerve. It may also lead to Volkmann’s ischaemic contracture caused by occlusion of the brachial artery (Figs 2.16a and b).
- The three bony points of the normal elbow form the equilateral triangle in a flexed elbow and are in one line in an extended elbow (Figs 2.17a and b).
• The humerus has a poor blood supply at the junction of its upper one-third and lower two-thirds. Fractures at this site show delayed union or non-union.

• The head of the humerus commonly dislocates inferiorly (subglenoid) (Fig. 2.18).

**RADIUS**

The radius is the lateral bone of the forearm, and is homologous with the tibia of the lower limb. It has an upper rounded end, a lower broad end with a styloid process and a shaft.

*Side Determination*

1. Upper end is having disc-shaped head, a narrow neck while lower end is expanded with a styloid process. Close to neck, it presents a radial tuberosity.
2. At the lower end, the anterior surface is in the form of thick prominent ridge. While the posterior surface presents four grooves for the extensor tendons.
3. Lower end presents a tubercle on the posterior surface called as dorsal tubercle of Lister.
4. The sharpest border of the shaft is the medial border.

*Features*

**Upper End**

1. The *head* is disc-shaped and is covered with hyaline cartilage (Fig. 2.19). It has a superior concave surface which articulates with the capitulum of the humerus at the elbow joint. The circumference of the head is also articular. It fits into a socket formed by the radial notch of the ulna and the *annular ligament*, thus forming the superior radioulnar joint.

2. The *neck* is enclosed by the narrow lower margin of the annular ligament. The head and neck are free from capsular attachment and can rotate freely within the socket.

3. The *radial tuberosity* lies just below the medial part of the neck. It has a rough posterior part and a smooth anterior part.

**Shaft**

It has three borders and three surfaces (Fig. 2.20).

*Borders*

1. The *anterior border* extends from the anterior margin of the radial tuberosity down close to the styloid process. It is oblique in the upper half of the shaft, and vertical in the lower half. The lowest part is sharp and crest-like. The oblique part is called the *anterior oblique line* (Fig. 2.19).
2. The *posterior border* is the mirror image of the anterior border, but is clearly defined only in its middle one-third. The upper oblique part is known as the *posterior oblique line* (Fig. 2.20).
3. The *medial or interosseous border* is the sharpest of the three borders. It extends from the radial tuberosity above to the posterior margin of the ulnar notch below. The interosseous membrane is attached to its lower three-fourths (Fig. 2.21a). In its lower part, it forms the posterior margin of an elongated triangular area (Fig. 2.22).

*Surfaces*

1. The *anterior surface* lies between the anterior and interosseous borders. A nutrient foramen opens in its upper part, and is directed upwards. The nutrient artery is a branch of the anterior interosseous artery (Fig. 2.19).
2. The *posterior surface* lies between the posterior and interosseous borders.
3. The *lateral surface* lies between the anterior and posterior borders. It shows a roughened area in its middle part.

**Lower End**

The lower end is the widest part of the bone. It has five surfaces.

1. The anterior surface is in the form of a thick prominent ridge. The *radial artery* is palpated against this surface.
2. The posterior surface presents four grooves for the extensor tendons. The dorsal tubercle of Lister lies lateral to an oblique groove (Fig. 2.20).
3. The *medial surface* is occupied by the *ulnar notch* for the head of the ulna (Fig. 2.20).
4. The *lateral surface* is prolonged downwards to form the styloid (Greek *pillar*) process (Fig. 2.20).
Fig. 2.19: Features of anterior surfaces of radius and ulna

Fig. 2.20: Features of right radius and ulna, posterior aspect

Figs 2.21a and b: (a) Radius (R) and ulna (U) in transverse section, and (b) tendons in six compartments/grooves (1–6) under the extensor retinaculum
The inferior surface bears a triangular area for the scaphoid bone, and a medial quadrangular area for the lunate bone. This surface takes part in forming the wrist joint (see Fig. 10.24).

**Attachments**

1. The *biceps* (Latin *two heads*) *brachii* is inserted into the rough posterior part of the radial tuberosity. The anterior part of the radial tuberosity is covered by a bursa (Figs 2.22 and 8.4).
2. The *supinator* (Latin *to bend back*) is inserted into the upper part of the lateral surface (Fig. 2.23).
3. The *pronator teres* is inserted into the middle of the lateral surface (Fig. 2.22).
4. The *brachioradialis* is inserted into the lowest part of the lateral surface just above the styloid process (Fig. 2.22).
5. The radial head of the *flexor digitorum superficialis* takes origin from the anterior oblique line and the upper part of anterior border (Fig. 2.22).
6. The *flexor pollicis* (Latin *thumb*) *longus* takes origin from the upper two-thirds of the anterior surface (Fig. 2.22).
7. The *pronator quadratus* is inserted into the lower part of the anterior surface and into the triangular area on the medial side of the lower end. The radial artery is palpated for ‘radial pulse’, as it lies on the...
The abductor pollicis longus and the extensor pollicis brevis arise from the posterior surface (Fig. 2.23).

The quadrate ligament is attached to the medial part of the neck.

The oblique cord is attached on the medial side just below the radial tuberosity (Fig. 2.22).

The articular capsule of the wrist joint is attached to the anterior and posterior margins of the inferior articular surface.

The articular disc of the inferior radioulnar joint is attached to the lower border of the ulnar notch (see Fig. 10.24).

The extensor retinaculum is attached to the lower part of the sharp anterior border (see Fig. 9.52b).

The interosseous membrane is attached to the lower three-fourths of the interosseous border.

The first groove between sharp crest-like lowest part of anterior border and styloid process gives passage to abductor pollicis longus and extensor pollicis brevis (Fig. 2.21b).

The second groove between styloid process and dorsal tubercle gives way to extensor carpi radialis longus and extensor carpi radialis brevis tendons.

The third oblique groove medial to dorsal tubercle gives passage to extensor pollicis longus tendon.

The fourth groove on the medial aspect gives passage to tendons of extensor digitorum, extensor indicis, posterior interosseous nerve and anterior interosseous artery.

In addition, at the junction of lower ends of radius and ulna, the fifth groove gives passage to the tendon of extensor digiti minimi.

Lastly in relation to ulna, between its head and styloid process is the sixth groove, traversed by the tendon of extensor carpi ulnaris (Fig. 2.21b).

These are six compartments/grooves under extensor retinaculum of wrist, four are in relation to radius, 5th at the junction of radius and ulna and 6th on the ulna itself between its head and styloid process (Fig. 2.21b).

OSSIFICATION

- The shaft of radius ossifies from a primary centre which appears during the 8th week of development.
- The lower end ossifies from a secondary centre which appears during the first year and fuses with shaft at 20th year; it is the growing end of the bone.
- The upper end (head) ossifies from a secondary centre which appears during the 4th year and fuses with shaft at 18th year (Table 2.1).

CLINICAL ANATOMY

- The radius commonly gets fractured about 2 cm above its lower end (Colles’ fracture). This fracture is caused by a fall on the outstretched hand (Fig. 2.24a). The distal fragment is displaced upwards and backwards, and the radial styloid process comes to lie proximal to the ulnar styloid process. (It normally lies distal to the ulnar styloid process.) If the distal fragment gets displaced anteriorly, it is called Smith’s fracture (Fig. 2.24b).
- A sudden powerful jerk on the hand of a child may dislodge the head of the radius from the grip of the annular ligament. This is known as subluxation of the head of the radius (pulled elbow) (Figs 2.25a and b). The head can normally be felt in a hollow behind the lateral epicondyle of the humerus.

Figs 2.24a and b: (a) Colles’ fracture with dinner fork deformity, and (b) Smith’s fracture

Figs 2.25a and b: (a) Position of bones, and (b) pulled elbow
The ulna is the medial bone of the forearm, and is homologous with the fibula of the lower limb. It has an upper end with two processes, a shaft and a narrow rounded lower end.

**Side Determination**

1. The upper end is hook-like, with its concavity directed forwards.
2. The lateral border of the shaft is sharp and crest-like.
3. Pointed styloid process lies posteromedial to the rounded head of ulna at its lower end.

**Features**

**Upper End**

The upper end presents the olecranon and coronoid processes, and the trochlear and radial notches (Fig. 2.19).

1. The olecranon process projects upwards from the shaft. It has superior, anterior, posterior, medial and lateral surfaces.
   - The anterior surface is articular, it forms the upper part of the trochlear notch (Fig. 2.19).
   - The posterior surface forms a triangular subcutaneous area which is separated from the skin by a bursa. Inferiorly, it is continuous with the posterior border of the shaft of the ulna (Fig. 2.20). Its upper part forms the point of the elbow.
   - The medial surface is continuous inferiorly with the medial surface of the shaft.
   - The lateral surface is smooth, continues as posterior surface of shaft.
   - The superior surface in its posterior part shows a roughened area.
2. The coronoid (Greek like crow’s beak) process projects forwards from the shaft just below the olecranon process and has four surfaces, namely superior, anterior, medial and lateral.
   - The superior surface forms the lower part of the trochlear notch.
   - The anterior surface is triangular and rough. Its lower corner forms the ulnar tuberosity.
   - The upper part of its lateral surface is marked by the radial notch for the head of the radius. The annular ligament is attached to the anterior and posterior margins of the notch. The lower part of the lateral surface forms a depressed area to accommodate the radial tuberosity. It is limited behind by a ridge called the supinator crest (Fig. 2.26).
   - Medial surface is continuous with medial surface of the shaft.
3. The trochlear notch forms an articular surface that articulates with the trochlea of the humerus to form the elbow joint.
4. The radial notch articulates with the head of the radius to form the superior radioulnar joint (Fig. 2.26).

**Shaft**

The shaft has three borders and three surfaces (Fig. 2.21).

**Borders**

1. The interosseous or lateral border is the sharpest in its middle two-fourths. Inferiorly, it can be traced to the lateral side of the head. Superiorly, it is continuous with the supinator crest.
2. The anterior border is thick and rounded. It begins above on the medial side of the ulnar tuberosity, passes backwards in its lower one-third, and terminates at the medial side of the styloid process.
3. The posterior border is subcutaneous. It begins, above, at the apex of the triangular subcutaneous area at the back of the olecranon process, and terminates at the base of the styloid process (Fig. 2.20).

**Surfaces**

1. The anterior surface lies between the anterior and interosseous borders. A nutrient foramen is seen on the upper part of this surface. It is directed upwards. The nutrient artery is derived from the anterior interosseous artery (Fig. 2.19).
2. The medial surface lies between the anterior and posterior borders (Fig. 2.19).
3. The posterior surface lies between the posterior and interosseous borders. It is subdivided into three areas by two lines. An oblique line divides it into upper and lower parts. The lower part is further divided by a vertical line into a medial and a lateral area.

**Lower End**

The lower end is made up of the head and the styloid process. The head articulates with the ulnar notch of the radius to form the inferior radioulnar joint. It is separated from the wrist joint by the articular disc.
The annular ligament of the superior radioulnar joint is attached to the two margins of radial notch of ulna (Fig. 2.26).

16. The ulnar collateral ligament of the wrist is attached to the styloid process.

17. The articular disc of the inferior radioulnar joint is attached by its apex to a small rough area just lateral to the styloid process (see Fig. 10.24).

OSSIFICATION

- The shaft and most of the upper end of ulna ossify from a primary centre which appears during the 8th week of development.
- The superior part of the olecranon process ossifies from a secondary centre which appears during the 10th year. It forms a scale-like epiphysis which joins the rest of the bone by 16th year.
- The lower end ossifies from a secondary centre which appears during the 5th year, and joins with the shaft by 18th year. This is the growing end of the bone (Table 2.1).

CLINICAL ANATOMY

- The ulna is the stabilising bone of the forearm, with its trochlear notch gripping the lower end of the humerus. On this foundation, the radius can pronate and supinate for efficient working of the upper limb.
- The shaft of the ulna may fracture either alone or along with that of the radius. Cross-union between the radius and ulna must be prevented to preserve pronation and supination of the hand.
- Dislocation of the elbow is produced by a fall on the outstretched hand with the elbow slightly flexed. The olecranon process shifts posteriorly and the elbow is fixed in slight flexion. Normally, in an extended elbow, the tip of the olecranon process lies in a horizontal line with the two epicondyles of the humerus; and in the flexed elbow, the three bony points form an equilateral triangle (Figs 2.17a and b). These relations are disturbed in dislocation of the elbow.
- Fracture of the olecranon process is common and is caused by a fall on the point of the elbow. Fracture of the coronoid process is uncommon, and usually accompanies dislocation of the elbow.
- Madelung’s deformity is dorsal subluxation (displacement) of the lower end of the ulna, due to retarded growth of the lower end of the radius (Fig. 2.27).
OSSIFICATION OF HUMERUS, RADIUS AND ULNA

Law of Ossification

In long bones possessing epiphyses at both their ends, the epiphysis of that end which appears first is last to join with the shaft. As a corollary, epiphysis which appears last is first to join.

These ends of long bones which unite last with the shaft are designated as growing end of the bone. In case of long bones of the upper limb, growing ends are at shoulder and wrist joints. This implies that the upper end of humerus and lower ends of both radius and ulna are growing ends; and each will, therefore, unite with its shaft at a later period than its corresponding other ends.

The direction of the nutrient foramen in these bones, as a rule, is opposite to the growing end.

The time of appearance and time of fusion (either of various parts at one end, or with the shaft) are given in Table 2.1.

Importance of Capsular Attachments and Epiphyseal Lines

Metaphysis is the epiphyseal end of the diaphysis. It is an actively growing part of the bone with rich blood supply. Infections in this part of the bone are most common in the young age. The epiphyseal line is the line of union of metaphysis with the epiphysis. At the end of the bone, besides the epiphyseal line, is the attachment of the capsule of the respective joints.

So, infection in the joint may affect the metaphysis of the bone, if it is partly or completely inside the joint capsule. As a corollary, the disease of the metaphysis, if inside a joint, may affect the joint. So, it is worthwhile to know the intimate relation of the capsular attachment and the epiphyseal line at the ends of humeral, radial and ulnar bones as shown in Table 2.2.

BONES

Upper Limb

Section 1

iii. The capitate (Latin head), and
iv. The hamate (Latin hook).

Identification
1. The scaphoid is boat-shaped and has a tubercle on its lateral side.
2. The lunate is half-moon-shaped or crescentic.
3. The triquetral is pyramidal in shape and has an isolated oval facet on the distal part of the palmar surface.
4. The pisiform is pea-shaped and has only one oval facet on the proximal part of its dorsal surface.
5. The trapezium is quadrangular in shape, and has a crest and a groove anteriorly. It has a sellar (concavo-convex) articular surface distally.
6. The trapezoid resembles the shoe of a baby.
7. The capitate is the largest carpal bone, with a rounded head.
8. The hamate is wedge-shaped with a hook near its base.

Side Determination

General Points
1. The proximal row is convex proximally, and concave distally.
2. The distal row is convex proximally and flat distally.
3 Each bone has 6 surfaces.
   i. The palmar and dorsal surfaces are non-articular, except for the triquetral and pisiform.
   ii. The lateral surfaces of the two lateral bones (scaphoid and trapezium) are non-articular.
   iii. The medial surfaces of the three medial bones (triquetral, pisiform and hamate) are non-articular.

4 The dorsal non-articular surface is always larger than the palmar non-articular surface, except for the lunate, in which the palmar surface is larger than the dorsal.

The general points help in identifying the proximal, distal, palmar and dorsal surfaces in most of the bones. The side can be finally determined with the help of the specific points.

Specific Points

1 The scaphoid: The tubercle is directed laterally, forward and downwards.

2 The lunate:
   i. A small semilunar articular surface for the scaphoid is on the lateral side.
   ii. A quadrilateral articular surface for the triquetral is on the medial side.

3 The triquetral:
   i. The oval facet for the pisiform lies on the distal part of the palmar surface.
   ii. The medial and dorsal surfaces are continuous and non-articular.

4 The pisiform:
   i. The oval facet for the triquetral lies on the proximal part of the dorsal surface.
   ii. The lateral surface is grooved by the ulnar nerve.

5 The trapezium:
   i. The palmar surface has a vertical groove for the tendon of the flexor carpi radialis.
   ii. The groove is limited laterally by the crest of the trapezium.
   iii. The distal surface bears a sellar concavoconvex articular surface for the base of the first metacarpal bone.

Fig. 2.28: Skeleton of the right hand: Palmar aspect
6 The *trapezoid*:
   i. The distal articular surface is bigger than the proximal.
   ii. The palmar non-articular surface is prolonged laterally.

7 The *capitate*: The dorsomedial angle is the distal-most projection from the body of the capitate. It bears a small facet for the 4th metacarpal bone.

8 The *hamate*: The hook projects from the distal part of the palmar surface, and is directed laterally.

**Attachments**

There are four bony pillars at the four corners of the carpus. All attachments are to these four pillars (Fig. 2.28).

1 The tubercle of the scaphoid:
   i. The *flexor retinaculum*,
   ii. A few fibres of the *abductor pollicis brevis*.

2 The pisiform gives:
   i. Insertion to be *Flexor carpi ulnaris* (FCU). Pisiform is a sesamoid bone in tendon of FCU.
   ii. *Flexor retinaculum* and its superficial slip (see Fig. 9.15),
   iii. *Abductor digiti minimi* (Fig. 2.32b),
   iv. *Extensor retinaculum* (see Fig. 9.52).

3 The trapezium:
   i. The crest gives origin to the *abductor pollicis brevis*, *flexor pollicis brevis*, and *opponens pollicis*. These constitute muscles of the thenar eminence (Fig. 2.32b).
   ii. The edges of the groove give attachment to the two layers of the *flexor retinaculum*.
   iii. The lateral surface gives attachment to the lateral ligament of the wrist joint.
   iv. The groove lodges the tendon of the *flexor carpi radialis*.

4 The hamate:
   i. The tip of the hook gives attachment to the *flexor retinaculum* (see Fig. 9.15).
   ii. The medial side of the hook gives attachment to the *flexor digiti minimi* and the *opponens digiti minimi*.

**Articulations**

1 The scaphoid: Radius, lunate, trapezium, trapezoid capitate (Figs 2.32b and c).

2 The lunate: Radius, scaphoid, capitale, hamate and triquetral.

3 The triquetral: Pisiform, lunate, hamate and articular disc of the inferior radio-ulnar joint.

4 The pisiform articulates only with the triquetral.

5 The trapezium: Scaphoid, 1st and 2nd metacarpals and trapezoid.

6 The trapezoid: Scaphoid, trapezium, 2nd metacarpal and capitale.

7 The capitale: Scaphoid, lunate, hamate, 2nd, 3rd and 4th metacarpals and trapezoid.

8 The hamate: Lunate, triquetral, capitale, and 4th and 5th metacarpals.

**Competency achievement:** The student should be able to:

**AN 8.6** Describe scaphoid fracture and explain the anatomical basis of avascular necrosis.7

**OSSIFICATION**

The year of appearance of centre of ossification in the carpal bones is shown in Fig. 2.29.

**CLINICAL ANATOMY**

- *Fracture of the scaphoid* is quite common. The bone fractures through the waist at right angles to its long axis. The fracture is caused by a fall on the outstretched hand, or on the tips of the fingers. This causes tenderness and swelling in the anatomical snuffbox, and pain on longitudinal percussion of the thumb and index finger. The residual disability is more marked in the midcarpal joint than in the wrist joint. The importance of the fracture lies in its liability to non-union, and avascular necrosis of the body of the bone with pain in anatomical snuffbox.

  Normally, the scaphoid has two nutrient arteries, one entering the palmar surface of the tubercle and the other the dorsal surface of the body. Occasionally (13% of cases), both vessels enter through the tubercle or through the distal half of the bone. In such cases, fracture may deprive the proximal half of the bone of its blood supply leading to avascular necrosis (Fig. 2.30).

  It may be treated on the lines of osteoarthritis.

- *Dislocation of the lunate* may be produced by a fall on the acutely dorsiflexed hand with the elbow joint flexed. This displaces the lunate anteriorly, also leading to *carpal tunnel syndrome* like features (Figs 2.31a to c).

**METACARPAL BONES**

1 The metacarpal bones are 5 miniature long bones, which are numbered from lateral to the medial side (Fig. 2.28).

2 Each bone has a head placed distally, a shaft and a base at the proximal end.
   i. The head is round. It has an articular surface which extends more anteroposteriorly than laterally. It
**Fig. 2.29:** Ossification of lower ends of radius, ulna, carpal bones, metacarpals and phalanges

**Fig. 2.30:** Fracture of the scaphoid

**Fig. 2.31a to c:** (a) Normal position of nerves, (b) Dislocation of lunate leading to carpal tunnel syndrome, and (c) Ape-like deformity of the hand (flattened thenar eminence)
extends more on the palmar surface than on the dorsal surface. The heads of the metacarpal bones form the knuckles during flexion.

ii. The shaft is concave on the palmar surface. Its dorsal surface bears a flat triangular area in its distal part.

iii. The base is irregularly expanded (Fig. 2.32a).

A metacarpal bone can be distinguished from a metatarsal bone because of the differences given in Table 2.3.

Characteristics of Individual Metacarpal Bones

1st  a. It is the shortest and stoutest of all metacarpal bones (Fig. 2.32b).
    b. The base is occupied by a concavoconvex articular surface for the trapezium.
    c. The dorsal surface of the shaft is uniformly convex (Fig. 2.32c).
    d. The head is less convex and broader from side-to-side than the heads of other metacarpals. The ulnar and radial corners of the palmar surface show impressions for sesamoid bones.
    e. The first metacarpal bone (lying on a more anterior plane) is rotated medially through 90° relative to the other metacarpals. As a result of this rotation, the movements of the thumb take place at right angles to those of other digits.
    f. It does not articulate with any other metacarpal bone.

2nd  The base is grooved from before backwards. The medial edge of the groove is larger (Fig. 2.32a).

3rd  The base has a styloid process projecting up from the dorsolateral corner (Fig. 2.32a).

4th  The base has two small oval facets on its lateral side for the third metacarpal, and on its medial side it has a single elongated facet for the 5th metacarpal (Fig. 2.32a).

5th  The base has an elongated articular strip on its lateral side for the 4th metacarpal. The medial side of the base is non-articular and bears a tubercle.

Side Determination of Metacarpals

The proximal, distal, palmar and dorsal aspects of each metacarpal bone can be made out from what has been stated above. The lateral and medial sides can be confirmed by the following criteria.

1st  i. The anterolateral surface is larger than the anteromedial (Fig. 2.32b).
    ii. The medial edge of the groove on the base is deeper than the lateral edge.

2nd  i. The medial edge of the groove on the base is deeper than the lateral edge.
    ii. The medial side of the base bears an articular strip which is constricted in the middle.

3rd  i. The styloid process is dorsolateral.
    ii. The lateral side of the base bears an articular strip which is constricted in the middle.
    iii. The medial side of the base has two small oval facets for the 4th metacarpal.

4th  i. The lateral side of the base has two small oval facets for the 3rd metacarpal.
    ii. The medial side of the base has an elongated articular strip for the 5th metacarpal.

5th  i. The lateral side of the base has an elongated articular strip for the 4th metacarpal.
    ii. The medial side of the base is non-articular and has a tubercle.

Fig. 2.32a: Bases of I–V metacarpal bones
Figs 2.32b and c: Attachments on the skeleton of hand: (b) Anterior aspect, and (c) posterior aspect
Main Attachments of Metacarpals
The main attachments from shaft of metacarpals are of palmar and dorsal interossei muscles. **Palmar interossei** arise from one bone each except the 3rd metacarpal (Fig. 2.32b). **Dorsal interossei** arise from adjacent sides of two metacarpals (Fig. 2.32c). The other attachments are listed below.

**1st**
- a. The **opponent pollicis** is inserted on the radial border and the anterolateral surface of the shaft (Fig. 2.32b).
- b. The **abductor pollicis longus** is inserted on the lateral side of the base.
- c. The **first palmar interosseous** muscle arises from the ulnar side of the base.

**2nd**
- a. The **flexor carpi radialis** is inserted on a tubercle on the palmar surface of the base (Fig. 2.32b).
- b. The **extensor carpi radialis longus** is inserted on the dorsal surface of the base (Fig. 2.32c).
- c. The **oblique head of the adductor pollicis** arises from the palmar surface of the base.

**3rd**
- a. A slip from the **flexor carpi radialis** is inserted on the palmar surface of the base.
- b. The **extensor carpi radialis brevis** is inserted on the dorsal surface of the base, immediately beyond the styloid process.
- c. The **oblique head of the adductor pollicis** arises from the palmar surface of the base.
- d. The **transverse head of the adductor pollicis** arises from the distal two-thirds of the palmar surface of the shaft (Fig. 2.32b).

**4th**
- Only the **interossei** arise from it (Figs 2.32b and c).

**5th**
- a. The **extensor carpi ulnaris** is inserted on the tubercle at the base.
- b. The **opponent digiti minimi** is inserted on the medial surface of the shaft (Fig. 2.32b).

**Articulations at the Bases**

**1st**: With the trapezium forms saddle-shaped joint.
**2nd**: With the trapezium, the trapezoid, the capitate and the 3rd metacarpal (Fig. 2.32b and c).
**3rd**: With the capitate and the 2nd and 4th metacarpals.
**4th**: With the capitate, the hamate and the 3rd and 5th metacarpals.
**5th**: With the hamate and the 4th metacarpal.

**OSSIFICATION**
- The shafts ossify from one primary centre each, which appears during the 9th week of development.
- A secondary centre for the head appears in the 2nd–5th metacarpals, and for the base in the 1st metacarpal. It appears during the 2nd–3rd year and fuses with the shaft at about 16–18 years (Fig. 2.29).

**CLINICAL ANATOMY**
- Fracture of the base of the first metacarpal is called **Bennett’s fracture**. It involves the anterior part of the base, and is caused by a force along its long axis. The thumb is forced into a semiflexed position and cannot be opposed. The fist cannot be clenched (Fig. 2.33).
- The other metacarpals may also be fractured by direct or indirect violence. Direct violence usually displaces the fractured segment forwards. Indirect violence displaces them backwards (Fig. 2.34).
UPPER LIMB

PHALANGES

There are 14 phalanges in each hand, three for each finger and two for the thumb. Each phalanx has a base, a shaft and a head.

Base

In the proximal phalanx, the base is marked by a concave oval facet for articulation with the head of the metacarpal bone. In the middle phalanx, or a distal phalanx, it is marked by two small concave facets separated by a smooth ridge.

Shaft

The shaft tapers towards the head. The dorsal surface is convex from side-to-side. The palmar surface is flattened from side-to-side, but is gently concave in its long axis.

Head

In the proximal and middle phalanges, the head has a pulley-shaped articular surface. In the distal phalanges, the head is non-articular, and is marked anteriorly by a rough horseshoe-shaped tuberosity which supports the sensitive pulp of the finger/tip.

Attachments

1. Base of the distal phalanx
   a. The flexor digitorum profundus is inserted on the palmar surface (Fig. 2.32b).
   b. Two-side slips of digital expansion fuse to be inserted on the dorsal surface. These also extend the insertion of lumbrical and interossei muscles (Fig. 2.32c).

2. The middle phalanx
   a. The two slips of flexor digitorum superficialis are inserted on each side of the shaft (Fig. 2.32b).
   b. The fibrous flexor sheath is also attached to the side of the shaft.
   c. A major part of the extensor digitorum is inserted on the dorsal surface of the base through dorsal digital expansion (Fig. 2.32c).

3. The proximal phalanx
   a. The fibrous flexor sheath is attached to the sides of the shaft.
   b. On each side of the base, parts of the lumbricals and interossei are inserted.

4. In the thumb, the base of the proximal phalanx provides attachments to the following structures (Fig. 2.32b).
   a. The abductor pollicis brevis and flexor pollicis brevis are inserted on the lateral side.
   b. The adductor pollicis and the first palmar interosseous are inserted on the medial side.
   c. The extensor pollicis brevis is inserted on the dorsal surface (Fig. 2.32c).

5. In the little finger, the medial side of the base of the proximal phalanx provides insertion to the abductor digiti minimi and the flexor digiti minimi (Fig. 2.32b).

OSSIFICATION

- The shaft of each phalanx ossifies from a primary centre which appears during the 8th week of development in the distal phalanx, 10th week in the proximal phalanx and 12th week in the middle phalanx.
- The secondary centre appears for the base during 2–4 years and fuses with the shaft during 15–18 years (Fig. 2.29).

Fig. 2.35: Six digits (polydactyly)
FACTS TO REMEMBER

• Axillary, radial and ulnar nerves are intimately related to humerus and are liable to be injured.
• Radial pulse is felt close to the lower end of shaft of radius.
• Pisiform bone is a sesamoid bone in the tendon of flexor carpi ulnaris muscle.
• First metacarpal is the shortest, and strongest of metacarpals. It is situated at an angle to the other bones, thus permitting opposition of the thumb.
• Third metacarpal is the longest and the axis of abduction and adduction passes through its centre.

CLINICOANATOMICAL PROBLEM

A 50-year-old man fell off his bicycle. He heard a cracking noise and felt severe pain in his right shoulder region. He noted that the lateral part of the shoulder drooped and medial end of clavicle was elevated.

• Which is the common site of fracture of clavicle and why?
• Why did his shoulder droop down?

Ans: The clavicle gets fractured at the junction of medial two-thirds and lateral one-third. This is the weak point as it lies at the junction of two opposing curvatures.

The shoulder drooped down, because of the weight of the unsupported shoulder.

Frequently Asked Questions

1. Name the muscles attached to greater and lesser tubercles of humerus.
2. Name the muscles attached to medial border of scapula on the dorsal and costal surfaces.
3. Name the tendons present on the posterior surface of lower end of radius.
4. Name the muscles arising from the aponeurosis attached to the posterior border of ulna.
5. Name the attachment of deltoid and trapezius on the clavicle.
6. Name the attachment of flexor digitorum superficialis and flexor digitorum profundus muscles on the phalanges.

Multiple Choice Questions

1. Which of the following bones is the first one to start ossification?
   a. Ulna  
   b. Scapula  
   c. Clavicle  
   d. Humerus  
   c. Shaft of humerus  
   d. Radial tuberosity

2. Fracture of humerus at midshaft is likely to cause injury to which of the following nerves?
   a. Median  
   b. Radial  
   c. Ulnar  
   d. Musculocutaneous

3. Attachments of biceps brachii are to all of the following, except:
   a. Tip of coracoid process  
   b. Supraglenoid tubercle

4. All the following muscles are flexors of the wrist, except:
   a. Flexor carpi  
   b. Flexor digitorum  
   c. Pronator teres  
   d. Flexor carpi ulnaris

5. The axis of abduction/adduction of digits passes through centre of which digit?
   a. 2nd  
   b. 3rd  
   c. 4th  
   d. 5th

6. All are heads of triceps brachii, except:
   a. Long head  
   b. Short head  
   c. Lateral head  
   d. Medial head

Answers

1. c  
2. b  
3. c  
4. c  
5. b  
6. b

CLAVICLE

- Enumerate the peculiarities of the clavicle.
- What type of joint is sternoclavicular joint?
- What fascia is attached to the margins of subclavian groove?
- Which is the common site of fracture of clavicle and why?
- What is cleidocranial dysostosis?

SCAPULA

- What type of muscle is subscapularis?
• Name the muscle attached to medial border of costal surface of scapula.
• Name the muscles attached to coracoid process of scapula.
• Enumerate the arteries related to all three borders of scapula.
• What nerve lies deep to transverse ligament/suprascapular ligament? Name the muscles supplied by this nerve.
• What is ‘winging’ of the scapula?

**HUMERUS**
• Name the muscles attached to greater tubercle of humerus. Which nerves innervate these muscles?
• What muscle is attached to lateral lip of bicipital groove of humerus? Show its actions.
• Mark the attachments of two heads of biceps brachii muscle. Show its actions.
• Show the position of important nerves related to the humerus.
• Name the muscles attached to lateral supracondylar ridge of humerus.
• What muscle arises from the front of lower part of humerus? Name the nerves supplying this muscle.
• What leads to Volkmann’s ischaemic contracture?

**RADIUS**
• Where is the insertion of biceps brachii muscle. Show its actions?
• What muscle arises from anterior surface of radius? What type of muscle is it according to arrangement of its muscle fibres?
• Where is radial pulse felt in relation to radius?
• Name the tendons on the dorsal surface of radius.
• Which border of radius gives attachment to interosseous membrane? Name the functions of this membrane.
• Name the carpal bones which articulate with distal end of radius.
• What is Colles’ fracture?
• What causes the ‘pulled elbow’?

**ULNA**
• How many joints are formed between radius and ulna? What are the types of these joints?
• Which muscle is attached to maximum area of ulna? What type of muscle is it according to its nerve supply?
• Mark the attachment of anconeus muscle. What is its action?
• What tendon passes through the gap between head and styloid process of ulna?
• How does Madelung’s deformity occur?

**CARPUS**
• Name the carpal bones in order.
• What type of bone is pisiform? Name other bones of the same type.
• Name the tendon traversing through the groove on trapezium. Where is its insertion?
• Name the attachments of the flexor retinaculum.
• Name the structures passing deep to the flexor retinaculum.
• What is carpal tunnel syndrome?
• Where is the pain of scaphoid fracture felt?
• What leads to avascular necrosis of the scaphoid?

**METACARPUS**
• Name the peculiarities of 1st metacarpal bone.
• Where are the sesamoid bones placed in relation to the metacarpal bone?
• Which metacarpal does not give attachment to palmar interosseous? Which is smallest palmar interosseous?
• Where is the attachment of opponens pollcis muscle? What is its action?
• Which muscle is attached to the palmar surface of shaft of 3rd metacarpal?
• Where is the attachment of opponens pollicis muscle?
• What is ‘Bennett’s fracture’?
• What is polydactyly?
• What is the importance of 3rd metacarpal?

**PHALANGES**
• Which muscle is inserted into the palmar surface of base of distal phalanx?
• Slips of which expansion are attached into the dorsal surface of base of distal phalanx?
• Slips of which muscle are attached on each side of the shaft of middle phalanx?
• Slip of which muscle is attached do the dorsal surface of base of middle phalanx?
• Name the muscles attached on each side of the base of proximal phalanx.
• What is buddy splint?
INTRODUCTION

The pectoral region lies on the front of the chest. It essentially consists of structures which connect the upper limb to the anterolateral chest wall. Breast lies in this region.

Competency achievement: The student should be able to:

**AN 13.6** Identify and demonstrate important bony landmarks of upper limb: Jugular notch, sternal angle, acromial angle, spine of the scapula, vertebral level of the medial end, inferior angle of the scapula.¹

SURFACE LANDMARKS

The following features of the pectoral region can be seen or felt on the surface of body.

1. The **clavicle** lies horizontally at the root of the neck, separating it from the front of the chest. The bone is subcutaneous, and therefore, palpable throughout its length. Medially, it articulates with the sternum at the **sternoclavicular joint**, and laterally with the acromion process at the **acromioclavicular joint**. Both the joints are palpable because of the upward projecting ends of the clavicle (Fig. 3.1). The sternoclavicular joint may be masked by the sternocleidomastoid muscle.

2. The **jugular notch** (interclavicular or suprasternal notch) lies between the medial ends of the clavicles, at the superior border of the manubrium sterni.

3. The **sternal angle** (angle of Louis) is felt as a transverse ridge about 5 cm below the jugular notch (Fig. 3.1). It marks the manubriosternal joint. Laterally, on either side, the **second costal cartilage** joins the sternum at this level. The sternal angle thus serves as a landmark for identification of the second rib. Other ribs can be identified by counting downwards from the second rib.

4. The **epigastric fossa** (pit of the stomach) is the depression in the infrasternal angle. The fossa overlies the xiphoid process, and is bounded on each side by the seventh costal cartilage.

5. The **nipple** is markedly variable in position in females. In males, and in immature females, it usually lies in the fourth intercostal space just medial to the midclavicular line; or 10 cm from the midsternal line. In fact, the position of the nipple is variable even in males.

6. The **midclavicular line** passes vertically through the middle of clavicle, the tip of the ninth costal cartilage and the inguinal point.
The infraclavicular fossa (deltopectoral triangle) is a triangular depression below the junction of the lateral and middle thirds of the clavicle. It is bounded medially by the pectoralis major, laterally by the anterior fibres of the deltoid, and superiorly by the clavicle.

The tip of the coracoid process of the scapula lies 2–3 cm below the clavicle, overlapped by the anterior fibres of the deltoid. It can be felt on deep palpation just lateral to the infraclavicular fossa.

The acromion process (acron = summit; omos = shoulder) is a flattened piece of bone that lies subcutaneously forming the top of the shoulder. The posterior end of its lateral border is called the acromial angle, where it is continuous with the lower lip of the crest of the spine of the scapula. The anterior end of its medial border articulates with the clavicle at the acromioclavicular joint.

The deltoid is triangular muscle with its apex directed downwards. It forms the rounded contour of the shoulder, extending vertically from the acromion process to the deltoid tuberosity of the humerus.

The axilla (Latin armpit) is a pyramidal space between the arm and chest. When the arm is raised (abducted), the floor of the axilla rises, the anterior and posterior folds stand out, and the space becomes more prominent. The anterior axillary fold contains the lower border of the pectoralis major, and posterior axillary fold contains the tendon of the latissimus dorsi winding round the fleshy teres major.

The medial wall of the axilla is formed by the upper 4 ribs covered by the serratus anterior. The narrow lateral wall presents the upper part of the humerus covered by the short head of the biceps, and the coracobrachialis. Axillary arterial pulsations can be felt by pressing the artery against the humerus. The cords of the brachial plexus can also be rolled against the humerus. The head of the humerus can be felt by pressing the fingers upwards into the axilla.

The midaxillary line is a vertical line drawn midway between the anterior and posterior axillary folds.

**DISSECTION**

Mark the following points.

- Centre of the suprasternal notch
- Xiphoid process
- 7 o’clock position at the margin of areola (left side), and 5 o’clock position at the margin of areola (right side)
- Lateral end of clavicle (Fig. 3.2)

Give an incision vertically down from the first point to the second which joins the centre of the suprasternal notch to the xiphoid process in the midsagittal plane. From the lower end of this line, extend the incision upward and laterally till you reach to the third point on the areolar margin.

Encircle the areola and carry the incision upwards and laterally till the anterior axillary fold is reached.

Continue the line of incision downwards along the medial border of the upper arm till its junction of upper one-third and lower two-thirds. Extend this incision transversely across the arm (refer to BDC App).

Make another incision horizontally from the xiphoid process across the chest wall till the posterior axillary fold.

Lastly, give horizontal incision from the centre of suprasternal notch to the lateral (acromial) end of the clavicle.

Reflect the two flaps of skin towards the upper limb.

**SUPERFICIAL FASCIA**

The superficial fascia (Latin a band) of the pectoral region is visualised after the skin has been incised. It contains moderate amount of fat, and is continuous with that of surrounding regions. The breast, which is well developed in females, is the most important of all contents of this fascia. The fibrous septa given off by the fascia support the lobes of the gland, and the skin covering the gland.

**Contents**

In addition to fat, the superficial fascia of the pectoral region contains the following.

- Cutaneous nerves derived from the cervical plexus and from the intercostal nerves.
ii. Cutaneous branches from the internal thoracic and posterior intercostal arteries.

iii. The platysma (Greek broad).

iv. The breast.

**Cutaneous Nerves of the Pectoral Region**

The cutaneous nerves of the pectoral (Latin *pectus, chest*) region are as follows (Figs 3.3 and 3.4).

1. The **medial, intermediate and lateral supraclavicular nerves** are branches of the cervical plexus (C3, C4). They supply the skin over the upper half of the deltoïd and from the clavicle down to the second rib.

2. The **anterior and lateral cutaneous branches of the second to sixth intercostal nerves** supply the skin below the level of the second rib. The intercostobrachial nerve of T2 supplies the skin of the floor of the axilla and the upper half of the medial side of the arm (Fig. 3.3).

It is of interest to note that the area supplied by spinal nerves C3 and C4 directly meets the area supplied by spinal nerves T2 and T3. This is because of the fact that the intervening nerves (C5–C8 and T1) have been ‘pulled away’ to supply the upper limb. It may also be noted that normally the areas supplied by adjoining spinal nerves overlap, but because of what has been said above there is hardly any overlap between the areas supplied by C3 and C4 above and T2 and T3 below (Fig. 3.4).

**Cutaneous Vessels**

The cutaneous vessels are very small. The anterior cutaneous nerves are accompanied by the **perforating branches of the internal thoracic artery**. The second, third and fourth of these branches are large in females for supplying the breast. The lateral cutaneous nerves are accompanied by the **lateral cutaneous branches of the posterior intercostal arteries** (Fig. 3.8).

**Platysma**

The platysma (Greek broad) is a thin, broad sheet of subcutaneous muscle. The fibres of the muscle arise from the deep fascia covering the pectoralis major; run upwards and medially, crossing the clavicle and the side of the neck; and are inserted into the base of the mandible, and into skin over the posterior and lower part of the face. The platysma is supplied by a branch of the **facial nerve**. When the angle of the mouth is pulled down, the muscle contracts and wrinkles the skin of the neck. The platysma may protect the external jugular vein (which underlies the muscle) from external pressure.

**Competency achievement:** The student should be able to:

AN 9.2 Describe the location, extent, deep relations, structure, age changes, blood supply, lymphatic drainage, microanatomy and applied anatomy of breast.²

**BREAST**

The breast is the most important structure present in the pectoral region.
The breast is found in both sexes, but is rudimentary in the male. It is well developed in the female after puberty. It forms an important accessory organ of the female reproductive system, and provides nutrition to the newborn in the form of milk. Its shape may be hemispherical, conical, pyriform, pendulous or flat.

**Situation**

The breast lies in the superficial fascia of the pectoral region. It is divided into four quadrants, i.e. upper medial, upper lateral, lower medial and lower lateral. A small extension of the upper lateral quadrant, called the axillary tail of Spence, passes through an opening in the deep fascia and lies in the axilla (Fig. 3.5). The opening is called foramen of Langer. Its base is circular.

**Extent of the Base**

i. Vertically, it extends from the second to the sixth ribs.

ii. Horizontally, it extends from the lateral border of the sternum to the midaxillary line.

**Deep Relations**

The deep surface of the breast is related to the following structures in that order (Fig. 3.6).

1. The breast lies on the deep fascia (pectoral fascia) covering the pectoralis major.
2. Still deeper there are the parts of three muscles, namely the pectoralis major, the serratus anterior, and the external oblique muscle of the abdomen.
3. The breast is separated from the pectoral fascia by loose areolar tissue, called the retromammary space. Because of the presence of this loose tissue, the normal breast can be moved freely over the pectoralis major.

**Structure of the Breast**

The structure of the breast may be conveniently studied by dividing it into the skin, the parenchyma, and the stroma. The parenchyma is known as the mammary gland.
Skin

It covers the gland and presents the following features.

1. A conical projection, called the nipple, is present just below the centre of the breast at the level of the fourth intercostal space 10 cm from the midline. The nipple is pierced by 15 to 20 lactiferous ducts. It contains circular and longitudinal smooth muscle fibres which can make the nipple stiff or flatten it, respectively. It has a few modified sweat and sebaceous glands. It is rich in nerve supply and has many sensory end organs at the termination of nerve fibres.

2. The skin surrounding the base of the nipple is pigmented and forms a circular area called the areola. This region is rich in modified sebaceous glands, particularly at its outer margin. These become enlarged during pregnancy and lactation to form raised tubercles of Montgomery. Oily secretions of these glands lubricate the nipple and areola, and prevent them from cracking during lactation. Apart from sebaceous glands, the areola also contains some sweat glands, and accessory mammary glands. The skin of the areola and nipple is devoid of hair, and there is no fat subjacent to it. Below the areola lie lactiferous sinus where stored milk is seen.

Parenchyma (Mammary Gland)

Mammary gland is a compound tubuloalveolar gland which secretes milk. As it lies in superficial fascia, there is no capsule. Mammary gland is a modified sweat gland. The gland consists of 15 to 20 lobes. Each lobe is a cluster of alveoli, and is drained by a lactiferous duct. The lactiferous ducts converge towards the nipple and open on it. Near its termination, each duct has a dilatation called a lactiferous sinus (Figs 3.7a and b).

Stroma

It forms the supporting framework of the gland. It is partly fibrous and partly fatty.

The fibrous stroma forms septa, known as the suspensory ligaments of Cooper, which anchor the skin and gland to the pectoral fascia (Fig. 3.7a).

The fatty stroma forms the main bulk of the gland. It is distributed all over the breast, except beneath the areola and nipple.

Blood Supply

The mammary gland is extremely vascular. It is supplied by branches of the following arteries (Fig. 3.8).

1. Internal thoracic artery, a branch of the subclavian artery, through its perforating branches.
2. The lateral thoracic, superior thoracic and acromiothoracic (thoracoacromial) branches of the axillary artery.
3. Lateral branches of the posterior intercostal arteries.

The arteries converge on the breast and are distributed from the anterior surface. The posterior surface is relatively avascular.

The veins follow the arteries. They first converge towards the base of the nipple where they form an anastomotic venous circle, from where veins run in superficial and deep sets.

1. The superficial veins drain into the internal thoracic vein and into the superficial veins of the lower part of the neck.
2. The deep veins drain into the axillary and posterior intercostal veins.

Nerve Supply

The breast is supplied by the anterior and lateral cutaneous branches of the 4th to 6th intercostal nerves. The nerves convey sensory fibres to the skin, and
autonomic fibres to smooth muscle and to blood vessels. The nerves do not control the secretion of milk. Secretion is controlled by the hormone prolactin, secreted by the pars anterior of the hypophysis cerebri. The diagnosis and management of breast disease should be done carefully.

Competency achievement: The student should be able to:

AN 10.4 Describe the anatomical groups of axillary lymph nodes and specify their areas of drainage.

AN 10.7 Explain anatomical basis of enlarged axillary lymph nodes.

Lymphatic Drainage

Lymphatic drainage of the breast assumes great importance to the surgeon because carcinoma of the breast spreads mostly along lymphatics to the regional lymph nodes. The subject can be described under two heads—the lymph nodes, and the lymphatic vessels.

Lymph Nodes

Groups of lymph nodes are shown in Fig. 3.9.

Lymph from the breast drains into the following lymph nodes (Fig. 3.9).

1. The axillary lymph nodes, chiefly the anterior (or pectoral) group. The posterior, lateral, central and apical groups of nodes also receive lymph from the breast either directly or indirectly.

2. The anterior thoracic (parasternal) nodes which lie along the internal mammary (thoracic) vessels (Fig. 3.10).

3. Some lymph from the breast also reaches the suprACLavicular nodes, the cephalic (deltopectoral) node, the posterior intercostal nodes (lying in front of the heads of the ribs), the subdiaphragmatic and subperitoneal lymph plexuses.

Fig. 3.9: Lymph nodes draining the breast. Radial incision is shown to drain breast abscess

Lymphatic Vessels

1. The superficial lymphatics drain the skin over the breast except for the nipple and areola. The lymphatics pass radially to the surrounding lymph nodes (axillary, anterior thoracic, supraclavicular and cephalic).

2. The deep lymphatics drain the parenchyma of the breast. They also drain the nipple and areola (Fig. 3.11).

Some further points of interest about the lymphatic drainage are as follows.

1. About 75% of the lymph from the breast drains into the axillary nodes; 20% into the anterior thoracic
nodes; and 5% into the posterior intercostal nodes. Among the axillary nodes, the lymphatics end mostly in the anterior group (closely related to the axillary tail), and partly in the posterior and apical groups. Lymph from the anterior and posterior groups passes to the central and lateral groups, and through them to the apical group. Finally, it reaches the supraclavicular nodes.

2 The anterior thoracic nodes drain the lymph not only from the inner half of the breast, but from the outer half as well.

3 A plexus of lymph vessels is present deep to the areola. This is the subareolar plexus of Sappey (Fig. 3.11). Subareolar plexus and most of lymph from the gland drain into the anterior or pectoral group of lymph nodes.

4 The lymphatics from the deep surface of the gland pass through the pectoralis major muscle and the clavipectoral fascia to reach the apical nodes, and also to the anterior thoracic nodes (Fig. 3.12).

5 Lymphatics from the lower and inner quadrants of the breast may communicate with the subdiaphragmatic and subperitoneal lymph plexuses after crossing the costal margin and then piercing the anterior abdominal wall through the upper part of the linea alba.

6 Anterior and central groups of nodes are commonly involved in carcinoma breast.

Competency achievement: The student should be able to:
AN 9.3 Describe development of the breast.

Development of the Breast

1 The breast develops from an ectodermal thickening, called the mammary ridge, milk line, or line of Schultz (Fig. 3.13). This ridge extends from the axilla to the groin. It appears during the fourth week of intrauterine life, but in human beings, it disappears over most of its extent persisting only in the pectoral region. The gland is ectodermal, and the stroma mesodermal in origin.

2 The persisting part of the mammary ridge is converted into a mammary pit. Secondary buds (15–20) grow down from the floor of the pit. These buds divide and subdivide to form the lobes of the gland. The entire system is first solid, but is later canalised. At birth or later, the nipple is everted at the site of the original pit.
Growth of the mammary glands, at puberty, is caused by oestrogens. Apart from oestrogens, development of secretory alveoli is stimulated by progesterone and by the prolactin hormone of the hypophysis cerebri.

Developmental anomalies of the breast are:
- Amastia (absence of the breast),
- Athelia (absence of nipple),
- Polymastia (supernumerary breasts),
- Polythelia (supernumerary nipples),
- Gynaecomastia (development of breasts in a male) which occurs in Klinefelter’s syndrome.

**Histology of Breast**

The mammary glands are specialised accessory glands of the skin, which have evolved in mammals to provide nourishment to the young ones. Mammary gland consists of 15–20 lobes with the same number of ducts. Each lobe is made up of many lobules containing acini. Histologically, only lobules are discernible in the gland.

**Resting Phase in Non-Pregnant Adult Female**

The mammary gland in this phase consists mainly of ducts and their branches (Fig. 3.14). The stroma has connective tissue and fat cells.

The intralobular ducts are usually lined by low columnar epithelium resting on a basement membrane. The intralobular connective tissue which is derived from the papillary layer of the dermis is more cellular, containing fibroblasts.

The interlobular connective tissue, which lies between the ducts of adjacent lobules, is derived from the reticular layer of the dermis, and is more fibroreticular in nature. It contains fat lobules.

**Lactating Phase**

The gland is full of acini with minimum amount of connective tissue. Some acini are lined by tall columnar cells, others by normal columnar cells. The nucleus may be round or oval and is seen in the middle of the cell (Fig. 3.15). Droplets of fat accumulate near the free surface of the cell. Myoepithelial cells may be seen between the basement membrane and secretory cells.

Ducts are also seen, but they are fewer in number as compared to the acini. The bigger ducts are lined by stratified columnar or columnar epithelium.
node.' Abscesses may also form in the breast and may require drainage. The following facts are worthy of note.

- Incisions of breast are usually made radially to avoid cutting the lactiferous ducts (Fig. 3.9).
- Cancer cells may infiltrate the suspensory ligaments. The breast then becomes fixed. Contraction of the ligaments can cause retraction or puckering (folding) of the skin.
- Infiltration of lactiferous ducts and their consequent fibrosis can cause retraction of the nipple.
- Obstruction of superficial lymph vessels by cancer cells may produce oedema of the skin giving rise to an appearance like that of the skin of an orange (peau d'orange appearance) (Fig. 3.16).
- Because of communications of the superficial lymphatics of the breast across the midline, cancer may spread from one breast to the other (Fig. 3.17).
- Because of communications of the lymph vessels with those in the abdomen, cancer of the breast may spread to the liver, and cancer cells may ‘drop’ into the pelvis producing secondaries there (Fig. 3.17).
- Apart from the lymphatics, cancer may spread through the segmental veins. In this connection, it is important to know that the veins draining the breast communicate with the vertebral venous plexus of veins. Through these communications, cancer can spread to the vertebrae and to the brain (Fig. 3.18).
- Carcinoma usually arises from epithelium of large ducts.
- Self-examination of breasts:
  a. Inspect: Symmetry of breasts and nipples.
  b. Change in colour of skin.
  c. Retraction of nipple is a sign of cancer.
  d. Discharge from nipple on squeezing it.
  e. Palpate all four quadrants with palm of hand. Note any palpable lump.
  f. Raise the arm to feel lymph nodes in axilla.
- Mammogram may reveal cancerous mass (Fig. 3.19).
- Fine needle aspiration cytology is safe and quick method of diagnosis of lesion of breast.
The deep fascia covering the pectoralis major muscle is called the pectoral fascia. It is thin and closely attached to the muscle by numerous septa passing between the fasciculi of the muscle. It is attached superiorly to the clavicle, and anteriorly to the sternum. Superolaterally, it passes over the infraclavicular fossa and deltopectoral groove to become continuous with the fascia covering the deltoide. Inferolaterally, the fascia curves round the inferolateral border of the pectoralis major to become continuous with the axillary fascia. Inferiorly, it is continuous with the fascia over the thorax and the rectus sheath.

**Competency achievement:** The student should be able to:

**AN 9.1** Describe attachment, nerve supply and action of pectoralis major and pectoralis minor.

---

### DEEP FASCIA

The deep fascia covering the pectoralis major muscle is called the pectoral fascia. It is thin and closely attached to the muscle by numerous septa passing between the fasciculi of the muscle. It is attached superiorly to the clavicle, and anteriorly to the sternum. Superolaterally, it passes over the infraclavicular fossa and deltopectoral groove to become continuous with the fascia covering the deltoide. Inferolaterally, the fascia curves round the inferolateral border of the pectoralis major to become continuous with the axillary fascia. Inferiorly, it is continuous with the fascia over the thorax and the rectus sheath.

### MUSCLES OF THE PECTORAL REGION

**Introduction**

Muscles of the pectoral region are described in Tables 3.1 and 3.2, study them on the articulated skeleton. Some additional features are given below.

**Pectoralis Major**

**Structures under Cover of Pectoralis Major**

a. **Bones and cartilages:** Sternum, costal cartilages and ribs.

b. **Fascia:** Clavipectoral.

c. **Muscles:** Subclavius, pectoralis minor, serratus anterior, intercostals and upper parts of the biceps brachii and coracobrachialis.

d. **Vessels:** Axillary.

e. **Nerves:** Cords of brachial plexus with their branches.

---

Retracted nipple is a sign of tumour in the breast. Size of mammary gland can be increased by putting an implant inside the gland. The size can be reduced by breast reduction surgery.

Cancer of the mammary glands is the most common cancer in females of all ages. It is more frequently seen in postmenopausal females due to lack of oestrogen hormones.

Self-examination of the mammary gland is the only way for early diagnosis and appropriate treatment.

Mastectomy is the medical term for the surgical removal of one or both breasts, partially or completely. A mastectomy is usually carried out to treat breast cancer. Lumpectomy is the removal of only the tumour.

Radical mastectomy is a surgical procedure involving the removal of breast, underlying pectoral muscles and lymph nodes of the axilla as a treatment for advanced breast cancer.

**Bilaminar Tendon of Pectoralis Major**

The muscle is inserted by a bilaminar tendon into the lateral lip of the intertubercular sulcus of the humerus. The anterior lamina is thicker and shorter than the posterior. It receives two strata of muscle fibres: superficial fibres arising from the clavicle and deep fibres arising from the manubrium (Fig. 3.20).

The posterior lamina is thinner and longer than the anterior lamina. It is formed by fibres from the front of the sternum, 2nd–6th costal cartilages, sternal end of 6th rib and from the aponeurosis of the external oblique muscle of the abdomen. Out of these, only the fibres from the sternum and aponeurosis are twisted around the lower border of the rest of the muscle. The twisted fibres form the anterior axillary fold.

These fibres pass upwards and laterally to get inserted successively higher into the posterior lamina of the tendon. Fibres arising lowest, find an opportunity to get inserted the highest and form a crescentic fold which fuses with the capsule of the shoulder joint.

**Fig. 3.21**: The pectoralis minor and subclavius muscles
**Clinical Testing**

i. The clavicular head is made prominent by flexing the arm to a right angle. The sternocostal head can be tested by extending the flexed arm against resistance.

ii. Sterno-costal head is made prominent by abducting arm to 60° and then touching the opposite hip.

iii. Pressing the fists against each other makes the whole muscle prominent (Fig. 3.22b).

iv. Lifting a heavy rod makes clavicular part prominent (right arm). Depressing a heavy rod shows sternocostal part as prominent (left arm) (Fig. 3.22c).

**Clavipectoral Fascia**

Clavipectoral fascia is a fibrous sheet situated deep to the clavicular portion of the pectoralis major muscle. It extends from the clavicle above to the axillary fascia below (Fig. 3.23). Its upper part splits to enclose the subclavius muscle. The posterior lamina is fused to the investing layer of the deep cervical fascia and to the axillary sheath. Inferiorly, the clavipectoral fascia splits to enclose the pectoralis minor muscle (see Fig. 4.3). Medially, it is attached to external intercostal muscle of upper intercostal spaces and laterally to coracoid process. Below this muscle, it continues as the suspensory ligament which is attached to the dome of the axillary fascia, and helps to maintain it.

The clavipectoral fascia is pierced by the following structures.

i. Lateral pectoral nerve (Figs 3.12a and b).

ii. Cephalic vein.

---

**Fig. 3.22a:** Nerve supply of pectorals, subclavius and serratus anterior

**Fig. 3.22b and c:** Pectoralis major being tested

**Fig. 3.23:** Clavipectoral fascia
iii. Thoracoacromial artery.
iv. Lymphatics passing from the breast and pectoral region to the apical group of axillary lymph nodes (Fig. 3.12a).

Competency achievement: The student should be able to:
AN 10.11 Describe and demonstrate attachment of serratus anterior with its action.7

Serratus Anterior
Serratus anterior muscle is not strictly muscle of the pectoral region, but it is convenient to consider it here. It is also called boxer’s muscle/swimmer’s muscle.

Origin
Serratus anterior muscle arises by eight digitations from the upper 8 ribs in the midaxillary plane and from the fascia covering the intervening intercostal muscles. The first digitation appears in the posterior triangle of neck. It arises from the outer border of 1st rib and from a rough impression on the 2nd rib. Also 5th–8th digitations interdigitate with the costal origin of external oblique muscle of abdomen.

Insertion
All 8 digitations pass backwards around the chest wall.

The muscle is inserted into the costal surface of the scapula along its medial border.

The first digitation is inserted from the superior angle to the root of the spine.

The next two digitations are inserted lower down on the medial border.

The lower five digitations are inserted into a large triangular area over the inferior angle (Fig. 3.25).

Nerve Supply
The nerve to the serratus anterior is a branch of the brachial plexus. It arises from roots C5, C6 and C7 and is also called long thoracic nerve. The nerve enters through the apex of axilla behind 1st part of axillary artery to reach the medial wall of axilla. It lies on the surface of the muscle (Figs 3.22a and 3.24a).

- C5 root supplies 1st and 2nd digitations.
A 45-year-old woman complained of a firm painless mass in the upper lateral quadrant of her left breast. The nipple was also raised. Axillary lymph nodes were palpable and firm. It was diagnosed as cancer breast.

- Where does the lymph from upper lateral quadrant drain?
- What causes the retraction of the nipple?

**Ans:**

The lymph from the upper lateral quadrant drains mainly into the pectoral group of axillary lymph nodes. The lymphatics also drain into supraclavicular and infraclavicular lymph nodes. Blockage of some lymph vessels by the cancer cells causes oedema of skin with dimpled appearance. This is called **peau d’orange**. When cancer cells invade the suspensory ligaments, glandular tissue or the ducts, there is retraction of the nipple.

**FURTHER READING**

- The largest series of the direct or indirect transfer of the sternal head of pectoralis major for insufficiency of serratus anterior in symptomatic scapular dyskinesia.

**Branches of any artery/nerve M-CAT**

- M — Muscular
- C — Cutaneous
- A — Articular
- T — Terminal

**FACTS TO REMEMBER**

- Pectoralis major forms part of the bed for the mammary gland. 75% of lymph from mammary gland drains into axillary; 20% into anterior thoracic and 5% into posterior intercostal lymph nodes.
- The sternocostal head of pectoralis major causes extension of the flexed arm against resistance.
- Pectoralis minor divides the axillary artery into three parts.

**Mnemonics**

- Branches of any artery/nerve M-CAT
- M — Muscular
- C — Cutaneous
- A — Articular
- T — Terminal

**DISSECTION**

Identify the extensive pectoralis major muscle in the pectoral region and the prominent deltoid muscle on the lateral aspect of the shoulder joint and upper arm.

Demarcate the deltopectoral groove by removing the deep fascia. Now identify the cephalic vein, a small artery and a few lymph nodes in the groove.

Clean the fascia over the pectoralis major muscle and look for its attachments. Divide the clavicular head of the muscle and reflect it laterally. Medial and lateral pectoral nerves will be seen supplying the muscle.

Make a vertical incision 5 to 6 cm from the lateral border of sternum and reflect its sternocostal head laterally.

Identify the pectoralis minor muscle under the central part of the pectoralis major. Note clavipectoral fascia extending between pectoralis minor muscle and the clavicle bone (refer to BDC App).

Identify the structures piercing the clavipectoral fascia: These are cephalic vein, thoracoacromial artery and lateral pectoral nerve. If some fine vessels are also seen, these are the lymphatic channels.

Also, identify the serratus anterior muscle showing serrated digitations on the side of the chest wall.

**Additional Features**

1. Paralysis of the serratus anterior produces ‘wringing of scapula’ in which the inferior angle and the medial border of the scapula are unduly prominent. The patient is unable to do any pushing action, nor can he raise his arm above the head. Any attempt to do these movements makes the inferior angle of the scapula still more prominent.

2. **Clinical testing**: Forward pressure with the hands against a wall, or against resistance offered by the examiner, makes the medial border and the inferior angle of the scapula prominent (wringing of scapula), if the serratus anterior is paralysed (see Fig. 2.12).

**CLINICOANATOMICAL PROBLEM**

Frequently Asked Questions

1. Describe mammary gland under following headings: Extent, relations, blood supply, lymphatic drainage and clinical anatomy.
2. Describe pectoralis major muscle under following headings: Origin, insertion, nerve supply, structures deep to it, actions and clinical anatomy.

Multiple Choice Questions

1. Which of the following muscles does not form deep relation of the mammary gland?
   a. Pectoralis major
   b. Pectoralis minor
   c. Serratus anterior
   d. External oblique muscle of abdomen

2. One of the following structures does not pierce clavipectoral fascia:
   a. Cephalic vein
   b. Thoracoacromial artery
   c. Medial pectoral nerve
   d. Lateral pectoral nerve

3. Which of the following arteries does not supply the mammary gland?
   a. Superior thoracic
   b. Thoracodorsal branch of subscapular artery
   c. Lateral thoracic artery
   d. Thoracoacromial artery

4. Axillary sheath is derived from which fascia?
   a. Pretracheal
   b. Prevertebral
   c. Investing layer of cervical
   d. Pharyngobasilar

5. Winging of scapula occurs in paralysis of:
   a. Pectoralis major
   b. Pectoralis minor
   c. Latissimus dorsi
   d. Serratus anterior

Answers

1. b  2. c  3. b  4. b  5. d

VIVA VOCE

- Name the cutaneous nerves innervating the skin of pectoral region.
- What muscles form the deep relations of the mammary gland?
- What is axillary tail and what is its importance?
- Where does the lymph from breast drain?
- Name the arteries supplying the breast.
- What structures pierce the clavipectoral fascia?
- What is peau d’orange appearance of the skin overlying the breast?
- How can cancer of one breast spread to other breast; to abdomen or pelvis or spread to cranial cavity?
- How does one examine the clavicular and sternocostal heads of pectoralis major muscle?
- How is the integrity of serratus anterior muscle tested?
- Which muscle divides the axillary artery in three parts?
Axilla

*Sailors know about the asymmetry of the arm and stitch the right sleeve a little looser than left.*
—Anonymous

**Competency achievement:** The student should be able to:

**AN 10.1** Identify and describe boundaries and contents of axilla.¹

**INTRODUCTION**

The axilla (Latin *armpit*) is a pyramidal space situated between the upper part of the arm and the chest wall. It resembles a four-sided pyramid, and has the following.

i. An apex  
ii. A base  
iii. Four walls: Anterior, posterior, medial and lateral.

The axilla is disposed obliquely in such a way that the apex is directed upwards and medially towards the root of the neck, and the base is directed downwards (Figs 4.1a and b).

**DISSECTION**

Place a rectangular wooden block under the neck and shoulder region of cadaver (Fig. 4.1). Ensure that the block supports the body firmly. Abduct the limb at right angles to the trunk; and strap the wrist firmly on block projecting towards your side. In continuation with earlier dissection, reflect the lower skin flap till the posterior axillary fold, made up by the subscapularis, teres major, and latissimus dorsi muscles, is seen. Clean the fat, and remove the lymph nodes and superficial veins to reach depth of the armpit. Identify two muscles arising from the tip of the coracoid process of scapula; out of these, the short head of biceps brachii muscle lies on the lateral side and the coracobrachialis on the medial side (*refer to BDC App*).

The pectoral muscles with the clavipectoral fascia form anterior boundary of the region.

Look for upper three intercostal muscles and serratus anterior muscle which make the medial wall of axilla.

Clean and identify the axillary vessels. Trace the course of the branches of the axillary artery.

**BOUNDARIES**

**Apex/Cervicoaxillary Canal**

It is directed upwards and medially towards the root of the neck.
It is truncated (not pointed), and corresponds to a triangular interval bounded:

i. Anteriorly, by the posterior surface of clavicle.
ii. Posteriorly, by the superior border of the scapula and medial aspect of coracoid process.
iii. Medially, it is bounded by the outer border of the first rib.

This oblique passage is called the cervicoaxillary canal (Figs 4.2a to c). The axillary artery, axillary vein and the brachial plexus enter the axilla through this canal.

**Base or Floor**

It is directed downwards, and is formed by skin, superficial and axillary fasciae. It is convex upwards in congruence with concavity of axilla.

**Anterior Wall**

It is formed by the following.

i. The pectoralis major in front (Fig. 4.3).
ii. The clavipectoral fascia
iii. Pectoralis minor.

**Posterior Wall**

It is formed by the following.

i. Subscapularis above (Fig. 4.4),
ii. Teres major, and
iii. Latissimus dorsi below.
**AXILLA**

53

**Infraclavicular part of the brachial plexus.**

**Five groups of axillary lymph nodes and the associated lymphatics.**

**The long thoracic and intercostobrachial nerves.**

**Axillary fat and areolar tissue in which the other contents are embedded.**

**Layout**

1. Axillary artery and the brachial plexus of nerves run from the apex to the base along the lateral wall of the axilla, nearer the anterior wall than the posterior wall.

2. The thoracic branches of the axillary artery lie in contact with the pectoral muscles, the lateral thoracic vessels running along the lower border of the pectoralis minor (Fig. 4.10a).

3. a. The subscapular vessels run along the lower border of the subscapularis.

   b. The subscapular nerves and the thoracodorsal nerve (nerve to latissimus dorsi) cross the anterior surface of the subscapularis (Fig. 4.4).

   c. The circumflex scapular vessels wind round the lateral border of the scapula (see Fig. 6.12).

   d. The axillary nerve and the posterior circumflex humeral vessels pass backwards close to the surgical neck of the humerus.

4. a. The medial wall of the axilla is avascular, except for a few small branches from the superior thoracic artery.

   b. The long thoracic nerve (nerve to the serratus anterior) descends on the surface of the muscle (Fig. 4.5).

   c. The intercostobrachial nerve pierces the antero-superior part of the medial wall and crosses the spaces to reach the medial side of the arm (see Fig. 3.3).

**Contents of Axilla**

1. Axillary artery and its branches (Figs 4.6 and 4.7).

2. Axillary vein and its tributaries.

**Fig. 4.4:** Muscles forming the posterior wall of axilla with their nerve supply

**Medial Wall**

It is convex laterally and formed by the following.

i. Upper four ribs with their intercostal muscles.

ii. Upper part of the serratus anterior muscle (Fig. 4.5).

**Lateral Wall**

It is very narrow because the anterior and posterior walls converge on it. It is formed by the following.

i. Upper part of the shaft of the humerus in the region of the bicipital groove, and

ii. Coracobrachialis and short head of the biceps brachii (Fig. 4.5).

**Fig. 4.5:** Walls and contents of axilla
The axillary lymph nodes are 20 to 30 in number, and are arranged in five sets:

a. The anterior group lies along the lower border of the pectoralis minor, on the lateral thoracic vessels.
b. The posterior group lies along the lower margin of the posterior wall along the subscapular vessels.
c. The lateral group lies posteromedial to the axillary vein (Fig. 4.11).
d. The central group lies in the fat of the axilla.
e. The apical group lies behind and above the pectoralis minor, medial to the axillary vein.

Clinical Anatomy

- The axilla has abundant axillary hair. Infection of the hair follicles and sebaceous glands gives rise to boils which are common in this area.

Competency achievement: The student should be able to:

AN 10.2 Identify, describe and demonstrate the origin, extent, course, parts, relations and branches of axillary artery and tributaries of vein.

Axillary Artery

Axillary artery is the continuation of the subclavian artery. It extends from the outer border of the first rib to the lower border of the teres major muscle where it continues as the brachial artery. Its direction varies with the position of the arm.

The pectoralis minor muscle crosses the artery and divides it into three parts (Fig. 4.6).

- First part, superior (proximal) to the muscle.
- Second part, posterior (deep) to the muscle.
- Third part, inferior (distal) to the muscle.

Relations of Axillary Artery

**Relations of First Part**

**Anterior**
1. Skin
2. Superficial fascia, platysma and supraclavicular nerves
3. Deep fascia
4. Clavicular part of the pectoralis major (Fig. 4.7a)
5. Clavpectoral fascia with cephalic vein, lateral pectoral nerve, and thoracoacromial artery.
6. Loop of communication between the lateral and medial pectoral nerves.

**Posterior**
1. First intercostal space with the external intercostal muscle.
2. First and second digitations of the serratus anterior with the nerve to serratus anterior.
3. Medial cord of brachial plexus with its medial pectoral branch.

**Fig. 4.6:** The extent and parts of the axillary artery

**Fig. 4.7a:** Diagrammatic relations of first part of axillary artery
**Lateral**
Lateral and posterior cords of the brachial plexus.

**Medial**
*Axillary vein:* The first part of the axillary artery is enclosed (together with the brachial plexus) in the axillary sheath, derived from the prevertebral layer of deep cervical fascia.

**Relations of Second Part**

**Anterior**
1. Skin
2. Superficial fascia
3. Deep fascia
4. Pectoralis major
5. Pectoralis minor (Fig. 4.7b)

**Fig. 4.7b:** Diagrammatic relations of second part of axillary artery

**Fig. 4.7c:** Diagrammatic relations of third part of axillary artery (upper part)

**Fig. 4.7d:** Diagrammatic relations of third part of axillary artery (lower part)
**Posterior**
1. Posterior cord of brachial plexus
2. Subscapularis

**Lateral**
1. Lateral cord of brachial plexus
2. Coracobrachialis (Fig. 4.8)

**Medial**
1. Medial cord of brachial plexus
2. Medial pectoral nerve
3. Axillary vein

**Relations of Third Part**

**Anterior**
1. Skin
2. Superficial fascia
3. Deep fascia
4. In the upper part, there are the pectoralis major and the medial root of the median nerve (Fig. 4.7c).

**Posterior**
1. Radial nerve (Fig. 4.9)
2. Axillary nerve in the upper part
3. Subscapularis in the upper part
4. Tendons of the latissimus dorsi and the teres major in the lower part (Fig. 4.7d).
Lateral
1. Coracobrachialis
2. Musculocutaneous nerve in the upper part (Fig. 4.8)
3. Lateral root of median nerve in the upper part
4. Trunk of median nerve in the lower part.

Medial
1. Axillary vein
2. Medial cutaneous nerve of the forearm and ulnar nerve, between the axillary artery and the axillary vein
3. Medial cutaneous nerve of arm, medial to the axillary vein (Fig. 4.9).

Branches
The axillary artery gives six branches. One branch arises from the first part, two branches from the second part, and three branches from the third part. These are as follows (Fig. 4.10).

Superior Thoracic Artery
Superior thoracic artery is a very small branch which arises from the first part of the axillary artery (near the subclavius). It runs downwards, forwards and medially, passes between the two pectoral muscles, and ends by supplying these muscles and the thoracic wall (Fig. 4.10).

Thoracoacromial (Acromiothoracic) Artery
Thoracoacromial artery is a branch from the second part of the axillary artery. It emerges at the upper border of the pectoralis minor, pierces the clavipectoral fascia, and soon divides into the following four terminal branches.
- a. The pectoral branch passes between the pectoral muscles, and supplies these muscles as well as the breast.
- b. The deltoid branch runs in the deltopectoral groove, along with the cephalic vein.
- c. The acromial branch crosses the coracoid process and ends by joining the anastomoses over the acromion process.
- d. The clavicular branch runs superomedially deep to the pectoralis major, and supplies the acromioclavicular joint and subclavius.

Lateral Thoracic Artery
Lateral thoracic artery is a branch of the second part of the axillary artery. It emerges at, and runs along, the lower border of the pectoralis minor in close relation with the anterior group of axillary lymph nodes.
In females, the artery is large and gives off the lateral mammary branches to the breast.
Subscapular Artery

Subscapular artery is the largest branch of the axillary artery, arising from its third part. It runs along the lower border of the subscapularis to terminate near the inferior angle of the scapula. It supplies the latissimus dorsi and the serratus anterior.

It gives off a large branch, the circumflex scapular artery, which is larger than the continuation of the main artery. This branch passes through the upper triangular intermuscular space, winds around the lateral border of the scapula between two slips of the teres minor, and gives a branch to the subscapular fossa, and another branch to the infraspinous fossa, both of which take part in the anastomoses around the scapula (see Fig. 6.12).

Anterior Circumflex Humeral Artery

Anterior circumflex humeral artery is a small branch arising from the third part of the axillary artery, at the lower border of the subscapularis.

It passes laterally in front of the intertubercular sulcus of the humerus, and anastomoses with the posterior circumflex humeral artery, to form an arterial circle round the surgical neck of the humerus.

It gives off an ascending branch which runs in the intertubercular sulcus, and supplies the head of the humerus and shoulder joint (Fig. 4.10b).

Posterior Circumflex Humeral Artery

Posterior circumflex humeral artery is much larger than the anterior artery. It arises from the third part of the axillary artery at the lower border of the subscapularis. It runs backwards, accompanied by the axillary nerve, passes through the quadrangular intermuscular space, and ends by anastomosing with the anterior circumflex humeral artery around the surgical neck of the humerus (see Figs 6.6 and 6.12).

It supplies the shoulder joint, the deltoid, and the muscles bounding the quadrangular space.

It gives off a descending branch which anastomoses with the ascending branch of the profunda brachii artery.

Anastomoses and Collateral Circulation

The branches of the axillary artery anastomose with one another and with branches derived from neighbouring arteries (internal thoracic, intercostal, suprascapular, deep branch of transverse cervical, profunda brachii). When the axillary artery is blocked, a collateral circulation is established through the anastomoses around the scapula which links the first part of the subclavian artery with the third part of the axillary artery (apart from communications with the posterior intercostal arteries) (see Fig. 6.12).

CLINICAL ANATOMY

- Axillary arterial pulsations can be felt against the lower part of the lateral wall of the axilla.
  In order to check bleeding from the distal part of the limb (in injuries, operations and amputations), the artery can be effectively compressed against the humerus in the lower part of the lateral wall of the axilla.

AXILLARY VEIN

The axillary vein is the continuation of the basilic vein. The axillary vein is joined by the veinae comitantes of the brachial artery, a little above the lower border of the teres major. It lies on the medial side of the axillary artery (Fig. 4.9). At the outer border of the first rib, it becomes the subclavian vein. It receives 5 out of 6 tributaries corresponding to the branches of axillary artery and the cephalic vein. Veins accompanying branches of thoracoacromial artery drain directly into the cephalic vein.

Lateral thoracic vein of upper limb is joined to superficial epigastric vein of lower limb by thoracoepigastric vein enabling blood to return to heart in blockage of inferior vena cava (see Flowcharts 14.1 and 14.2).

Competency achievement: The student should be able to:

AN 10.4 Describe the anatomical groups of axillary lymph nodes and specify their areas of drainage.

AN 10.7 Explain anatomical basis of enlarged axillary lymph nodes.

AXILLARY LYMPH NODES

The axillary lymph nodes are scattered in the fibrofatty tissue of the axilla. They are divided into five groups.

1. The nodes of the anterior (pectoral) group lie along the lateral thoracic vessels, i.e. along the lower border of the pectoralis minor. They receive lymph from the upper half of the anterior wall of the trunk, and from the major part of the breast (Fig. 4.11).
2. The nodes of the posterior (scapular) group lie along the subscapular vessels on the posterior fold of the axilla. They receive lymph from the posterior wall of the upper half of the trunk, and from the axillary tail of the breast.
3. The nodes of the lateral group lie along the upper part of the humerus, medial to the axillary vein. They receive lymph from the upper limb.
4. The nodes of the central group lie in the fat of the upper axilla. They receive lymph from the preceding groups and drain into the apical group. They receive some direct vessels from the floor of the axilla. The intercostobrachial nerve is closely related to them.
5. The nodes of the apical or infraclavicular group lie deep to the clavipectoral fascia, along the axillary vessels.

Upper Limb

Section 1
**Fig. 4.13:** Mixed fibres of a spinal nerve

**Fig. 4.14:** The right brachial plexus
**Roots and Trunks—Supraclavicular Part**

Roots C5 and C6 join to form the upper trunk. Root C7 forms the middle trunk. Roots C8 and T1 join to form the lower trunk. These lie in the neck between scalenus anterior and scalenus medius muscles, carrying axillary sheath from prevertebral fascia (see Fig. 12.10).

**Divisions of the trunks—Retroclavicular Part**

Each trunk (three in number) divides into ventral and dorsal divisions (which ultimately supply the anterior and posterior aspects of the limb). These divisions join to form cords.

**Cords and Branches—Infraclavicular Part**

i. The lateral cord is formed by the union of ventral divisions of the upper and middle trunks (two divisions).

ii. The medial cord is formed by the ventral division of the lower trunk (one division).

iii. The posterior cord is formed by union of the dorsal divisions of all the three trunks (three divisions).

These are named according to relation of cords to the 2nd part of axillary artery.

**Sympathetic Innervation**

1. Sympathetic nerves for the upper limb are derived from spinal segments T2 to T6. Most of the vasoconstrictor fibres supplying the arteries emerge from segments T2 and T3.

2. The preganglionic fibres arise from lateral horn cells and emerge from the spinal cord through ventral nerve roots.

3. Passing through white rami communicantes, they reach the sympathetic chain.

4. They ascend within the chain and end in the middle cervical, inferior cervical and first thoracic ganglia.

5. Postganglionic fibres from middle cervical ganglion pass through grey rami communicantes to reach C5, and C6 nerve roots.

6. Postganglionic fibres from inferior cervical ganglion pass through grey rami communicantes to reach C7, and C8 nerve roots.

7. Postganglionic fibres from first thoracic sympathetic ganglion pass through grey rami communicantes to reach T1 nerve roots.

8. The arteries of skeletal muscles are dilated by sympathetic activity. For the skin, however, these nerves are vasomotor, sudomotor and pilomotor.

   **Vasomotor:** Constricts the arterioles of skin.

   **Sudomotor:** Increases the sweat secretion.

   **Pilomotor:** Contracts the arrector pili muscle to cause erection of the hair.

**Branches**

The roots value of each branch is given in brackets.

**Branches of the Roots**

The roots value of each branch is given in brackets.

1. Nerve to serratus anterior (long thoracic nerve) (C5–C7). It only supplies serratus anterior muscle, one of the key muscles, for overhead abduction.

2. Nerve to rhomboids (dorsal scapular nerve) (C5). This nerve supplies rhomboid minor and rhomboid major muscles, responsible for retraction of the shoulder girdle gives a branch to levator scapulae.

3. Branches to longus colli and scaleni muscles (C5–C8) and branch to phrenic nerve (C4). The root of phrenic nerve from C5 is small one, the main root is from C4. Phrenic nerve is the sole motor nerve supply of thoracoabdominal diaphragm. In addition, it carries afferent fibres from mediastinal pleura, fibrous pericardium and part of the parietal peritoneum.

**Branches of the Trunks**

These arise only from the upper trunk which gives two branches:

1. Suprascapular (C5, C6). This nerve supplies supraspinatus and infraspinatus muscles.

2. Nerve to subclavius (C5, C6). It supplies the small subclavius muscles. It may give a root for phrenic nerve.

**Branches of the Cords**

**Branches of lateral cord**

1. Lateral pectoral (C5–C7). This nerve supplies both pectoralis major and pectoralis minor muscles.

2. Musculocutaneous (C5–C7). This is the nerve of muscles of front of arm, i.e. coracobrachialis both the long and short heads of biceps brachii and the brachialis muscles.

3. Lateral root of median (C5–C7). It joins the medial root of median nerve. Median nerve is the chief nerve of the muscles of front of forearm and of muscles of thenar eminence.

**Branches of medial cord**

1. Medial pectoral (C8, T1). It also supplies both the pectoralis minor and pectoralis major muscles.

2. Medial cutaneous nerve of arm (C8, T1) carries sensory impulses from a small area of medial side of arm.

3. Medial cutaneous nerve of forearm (C8, T1) carries sensory impulses from large area of medial side of the forearm.

4. Ulnar (C7, C8, T1). C7 fibres reach by a communicating branch from lateral root of median nerve.
This is the nerve of one and a half muscles of front of forearm and 15 intrinsic muscles of the palm.

5 Medial root of median (C8, T1). It joins the lateral root and gets distributed with branches of median nerve.

Branches of posterior cord
1 Upper subscapular (C5, C6). This nerve supplies large multipennate subscapularis muscles.
2 Nerve to latissimus dorsi (C6–C8). Only supplies muscles of its name. It is also called thoracodorsal nerve.
3 Lower subscapular (C5, C6). It helps upper subscapular nerve in supplying of the subscapularis muscles. In addition, it supplies small teres minor muscle.
4 Axillary (circumflex) (C5, C6). It is responsible for supplying one of the important muscles of the shoulder, the deltoid. It also supplies small teres minor muscle.
5 Radial (C5–C8, T1). This is the thickest branch of brachial plexus. It supplies all the three heads of triceps brachii muscle. Then it supplies 12 muscles on the back of forearm.

In addition to the branches of the brachial plexus, the upper limb is also supplied, near the trunk, by the supraclavicular branches of the cervical plexus, and by the intercostobrachial branch of the second intercostal nerve. Sympathetic nerves are distributed through the brachial plexus. The arrangement of the various nerves in the axilla, was studied with the relations of the axillary artery.

Special Features
The lateral cord, medial cord and their branches form the letter ‘M’ with the three corners extended (Fig. 4.8 inset). Lateral cord gives musculocutaneous and lateral root of median.

Medial cord gives ulnar and medial root of median. The lateral and medial roots of median nerve join to form the median nerve.

Blood Supply of Brachial Plexus
Vertebral artery and thyrocervical trunk with its branches, the suprascapular and transverse cervical arteries, supply blood to the brachial plexus. These are the life line of this important plexus.

CLINICAL ANATOMY
Global total brachial plexus birth baby is the most severe type of paralysis.

Erb’s Paralysis
Site of injury: One region of the upper trunk of the brachial plexus is called Erb’s point (Fig. 4.15). Six nerves meet here. Injury to the upper trunk causes Erb’s paralysis.

Causes of injury: Undue separation of the head from the shoulder, which is commonly encountered in the following.
1. Birth injury/difficult childbirth
2. Fall on the shoulder
3. During anaesthesia.

Nerve roots involved: Mainly C5 and partly C6.
Muscles paralysed: Mainly biceps brachii, deltoid, brachialis and brachioradialis. Partly supraspinatus, infraspinatus and supinator.

Deformity and position of the limb:
• Arm: Hangs by the side; it is adducted and medially rotated.
• Forearm: Extended and pronated.

The deformity is known as ‘policeman’s tip hand’ or waiter’s tip hand or ‘porter’s tip hand’ (Fig. 4.16).

Disability: The following movements are lost.

AN 10.6 Explain the anatomical basis of clinical features of Erb’s palsy and Klumpke’s paralysis.
Abduction and lateral rotation of the arm at shoulder joint.
- Flexion and supination of the forearm.
- Biceps and supinator jerks are lost.
- Sensations are lost over a small area over the lower part of the deltoid.

**Klumpke’s Paralysis**

*Site of injury:* Lower trunk of the brachial plexus.

*Cause of injury:* Undue abduction of the arm, as in clutching something with the hands after a fall from a height, or sometimes in birth injury.

*Nerve roots involved:* Mainly T1 and partly C8.

*Muscles paralysed*
- Intrinsic muscles of the hand (T1).
- Ulnar flexors of the wrist and fingers (C8).

*Deformity and position of the hand:* Claw hand due to the unopposed action of the long flexors and extensors of the fingers. In a claw hand, there is hyperextension at the metacarpophalangeal joints and flexion at the interphalangeal joints.

*Disability:*
- Complete claw hand (Fig. 4.17).
- Cutaneous anaesthesia and analgesia in a narrow zone along the ulnar border of the forearm and hand.

**Horner’s syndrome:** If T1 is injured proximal to white ramus communicans to first thoracic sympathetic ganglion, there is ptosis, miosis, anhydrosis, enophthalmos, and loss of ciliospinal reflex—may be associated. This is because of injury to sympathetic fibres to the head and neck that leave the spinal cord through nerve T1 (Fig. 4.18).

*Vasomotor changes:* The skin area with sensory loss is warmer due to arteriolar dilation. It is also drier due to the absence of sweating as there is loss of sympathetic activity.

*Trophic changes:* Long-standing case of paralysis leads to dry and scaly skin. The nails crack easily with atrophy of the pulp of fingers.

**Injury to the Nerve to Serratus Anterior (Nerve of Bell)**

*Causes:*
1. Sudden pressure on the shoulder from above.
2. Carrying heavy loads on the shoulder.

*Deformity:* Winging of the scapula, i.e. excessive prominence of the medial border of the scapula. Normally, the pull of the muscle keeps the medial border against the thoracic wall.

*Disability:*
- Loss of pushing and punching actions. During attempts at pushing, there occurs winging of the scapula (see Fig. 2.12).
- Overhead abduction of shoulder girdle is partly affected due to intact trapezius muscle.

**Mnemonics**

*Brachial plexus: Branches of posterior cord*

**STAR:**
- Subscapular (upper and lower)
- Thoracodorsal
- Axillary
- Radial

*Axillary artery branches “Slap The Lawyer Save A Patient”:*
1st part gives 1 branch; 2nd part 2 branches; and 3rd part 3 branches.
Superior thoracic branch of 1st part
Thoracoacromial branch of 2nd part
Lateral thoracic branch of 2nd part
Subscapular branch of 3rd part
Anterior circumflex humeral branch of 3rd part
Posterior circumflex humeral branch of 3rd part

*Thoracoacromial artery branches “ABCD”:*
- Acromial
- Breast (pectoral)
- Clavicular
- Deltoid

*Brachial plexus branches: “My Aunt Ragged My Uncle”:*
From lateral to medial:
- Musculocutaneous
- Axillary
- Radial
- Median
- Ulnar

*Brachial plexus “Ramu Tailor Drinks Cold Beer”:*
- Roots (ventral rami) C5–T1
- Trunks (upper, middle, lower)
- Divisions (3 anterior and 3 posterior)
- Cords (lateral, posterior, medial)
- Branches

*Median nerve: Recognizing it in an opened axilla*
The Median nerve is the Middle of a giant capital “M” formed by the musculocutaneous and ulnar nerves.

*Pectoral nerves: Path of lateral versus medial*
"Lateral Less, Medial More".
Lateral pectoral nerve only goes through Pectoralis major, but Medial pectoral nerve goes through both Pectoralis major and minor.

*Serratus anterior: Innervation and action*
"C5–C7 raise your arms up to heaven".
Long thoracic nerve roots (C5–C7) innervate Serratus anterior.
Test C5–C7 roots clinically by ability to raise arm past 90°.

smooth anterior and posterior walls of the axilla are formed.
- Infracavicular part of brachial plexus lies in the axilla.
- Apex of the axilla is known as cervicoaxillary canal and gives passage to axillary vessels and lower part of brachial plexus.
- Axillary sheath is derived from prevertebral fascia.

**CLINICOANATOMICAL PROBLEM**
A patient came with inability to: (i) abduct right shoulder, (ii) flex elbow joint, and (iii) supinate the forearm
- What is the site of injury of the nerves?
- What is the point called?
- What are the nerves affected?

**Ans:** The site of injury is called Erb’s point.

Six nerves are involved:
- Ventral ramus of cervical five segment of spinal cord
- Ventral ramus of cervical six segment of spinal cord
These two rami join to form the upper trunk.
- Suprascapular nerve from upper trunk
- Nerve to subclavius from upper trunk
- Anterior division of upper trunk
- Posterior division of upper trunk
These divisions give fibres to deltoid, brachialis, biceps brachii, supinator, so the arm cannot be abducted. The elbow is extended and forearm is pronated. This paralysis is called Erb’s paralysis.

**FURTHER READING**
- Kuntz A. Distribution of the sympathetic rami to the brachial plexus: its relation to sympathectomy affecting the upper extremity. Arch Surg 1927;15:871–77. *A description of the significant number of individuals in whom the intrathoracic somatic branches from the second thoracic spinal nerve join the first thoracic spinal nerve. These 'Kuntz's nerves' join the lower part of the brachial plexus without passing through the stellate ganglion, explaining the incomplete sympathetic blockade of the upper extremities in stellate ganglion blockade.*
Frequently Asked Questions

1. Describe the axillary artery under following headings: Beginning, course and branches. Add a note on anastomoses around scapula.

2. Enumerate the roots, trunks, cords, divisions and branches of brachial plexus.

3. Write short notes/enumerate:
   a. Boundaries of axilla
   b. Areas draining into axillary lymph nodes
   c. Branches of posterior cord of brachial plexus
   d. Erb’s paralysis
   e. Klumpke’s paralysis

Multiple Choice Questions

1. Which of the following is not a branch of posterior cord of brachial plexus?
   a. Upper subscapular
   b. Lower subscapular
   c. Suprascapular
   d. Axillary

2. Porter’s tip or policeman’s tip deformity occurs due to:
   a. Klumpke’s paralysis
   b. Paralysis of median nerve
   c. Paralysis of radial nerve
   d. Erb’s paralysis

3. Which is not a branch of lateral cord of brachial plexus?
   a. Musculocutaneous
   b. Lateral root of median
   c. Medial root of median
   d. Lateral pectoral

4. Erb’s paralysis causes weakness of all muscles, except:
   a. Supraspinatus
   b. Deltoid
   c. Biceps brachii
   d. Triceps brachii

5. Posterior wall of axilla is formed by all muscles, except:
   a. Teres major
   b. Teres minor
   c. Latissimus dorsi
   d. Subscapularis

Answers

1. c  2. d  3. c  4. d  5. b

Viva Voce

- Name the muscles forming posterior wall of axilla. Which nerves supply these muscles.
- What are the boundaries of cervicoaxillary canal?
- Which muscle divides the axillary artery into 3 parts?
- What is the relation of the cords of brachial plexus to the 1st and 2nd parts of axillary artery?
- Name the branches of axillary artery.
- Which is the largest branch of axillary artery?
- Name the lymph nodes in the axilla.
- Which nerves form the brachial plexus?
- Which sympathetic ganglia give sympathetic fibers to the roots of brachial plexus?

- Name the branches from roots of BP (brachial plexus).
- Name the branches of lateral cord of BP.
- Name the branches of medial cord of BP.
- Name the branches of posterior cord of BP.
- Which is the thickest branch of brachial plexus?
- What is Erb’s point?
- What is the disability in Erb’s paralysis?
- What is the disability in Klumpke’s paralysis?
- What is Bell’s paralysis? How does one test this paralysis?
INTRODUCTION
This chapter deals mainly with structures which connect the upper limb with the back of the trunk.

SURFACE LANDMARKS

1 The scapula (shoulder blade) is placed on the posterolateral aspect of the upper part of the thorax. It extends from the second to seventh ribs. Although it is thickly covered by muscles, most of its outline can be felt in the living subject. The acromion process lies at the top of the shoulder. The crest of the spine of the scapula runs from the acromion process medially and slightly downwards to the medial border of the scapula. The medial border and the inferior angle of the scapula can also be palpated (Fig. 5.1).

2 The eighth rib is just below the inferior angle of the scapula. The lower ribs can be identified on the back by counting down from the eighth rib.

3 The iliac crest is a curved bony ridge lying below the waist. The anterior end of the crest is the anterior superior iliac spine. The posterior superior iliac spine is felt in a shallow dimple above the buttock, about 5 cm from the median plane.

4 The sacrum lies between the right and left dimples mentioned above. Usually three sacral spines are palpable in the median plane.

5 The coccyx lies between the two buttocks in the median plane.

6 The spine of the seventh cervical vertebra or vertebra prominens is readily felt at the root of the neck. Higher up on the back of the neck, the second cervical spine can be felt about 5 cm below the external occipital protuberance. Other spines that can be recognised are T3 at the level of root of the spine of the scapula, L4 at the level of the highest point of the iliac crest, and S2 at the level of the posterior superior iliac spine.

7 The junction of the back of the head with that of the neck is indicated by the external occipital protuberance and the superior nuchal lines. The external occipital protuberance is a bony projection felt in the median plane on the back of the head at the upper end of the nuchal furrow (running vertically on the back of the neck). The superior nuchal lines are indistinct curved ridges which extend on either side from the protuberance to the mastoid process. The nuchal furrow extends to the external occipital protuberance above and to the spine of C7 below.
SKIN AND FASCIAE OF THE BACK

Position

Human being mostly lies on his back. Therefore, the skin and fasciae of the back are adapted to sustain pressure of the body weight. Accordingly, the skin is thick and fixed to the underlying fasciae; the superficial fascia containing variable amount of fat, is thick and strong and is connected to overlying skin by connective tissue; and the deep fascia is dense in texture.

Cutaneous Nerves

The cutaneous nerves of the back are derived from the posterior primary rami of the spinal nerves. Their distribution extends up to the posterior axillary lines. The following points may be noted.

1. The posterior primary rami of the spinal nerves C1, C7, C8, and L4, 5 do not give off any cutaneous branches. All twelve thoracic, L1–3 and five sacral nerves, however, give cutaneous branches.

2. Each posterior/dorsal primary ramus divides into medial and lateral branches, both of which supply the erector spinae muscles, but only one of them, either medial or lateral, continues to become the cutaneous nerves. In the upper half of the body (up to T6), the medial branches, and in the lower half of the body (below T6) the lateral branches, of the posterior primary rami provide the cutaneous branches. Each cutaneous nerve divides into a smaller medial and a larger lateral branch before supplying the skin (Fig. 5.2).

3. The posterior primary rami supply the intrinsic muscles of the back and the skin covering them. The cutaneous distribution extends further laterally than the extensor muscles.

4. No posterior primary ramus ever supplies skin or muscles of a limb. The cutaneous branches of the posterior primary rami of nerves L1, 2, 3 and S1–3 are exceptions in this respect: They turn downwards unlike any other nerve and supply the skin of the gluteal region.

DISSECTION

Identify the external occipital protuberance (i) of the skull. Draw a line in the midline from the protuberance to the spine of the last thoracic (T12) vertebra (ii). Make incision along this line (Fig. 5.1). Extend the incision from its lower end to the deltoid tuberosity (iii) on the humerus which is present on lateral surface about the middle of the arm. Note that the arm is placed by the side of the trunk. Make another incision along a horizontal line from seventh cervical spine—vertebra prominens (iv) to the acromion process of scapula (v). Reflect the skin flap laterally.

Fig. 5.2: Typical thoracic spinal nerve. The ventral primary ramus is the intercostal nerve.
Features
Muscles connecting the upper limb with the vertebral column are the trapezius (Figs 5.3a and b), the latissimus dorsi, the levator scapulae, and the rhomboid minor and rhomboid major. The attachments of these muscles are given in Table 5.1, and their nerve supply and actions are shown in Table 5.2.

Competency achievement: The student should be able to:

AN 10.8 Describe, identify and demonstrate the position, attachment, nerve supply and actions of trapezius and latissimus dorsi.¹

MUSCLES CONNECTING THE UPPER LIMB WITH THE VERTEBRAL COLUMN

Dissection
Identify the attachments of trapezius muscle in the upper part of back; and that of latissimus dorsi in the lower part. Cut vertically through trapezius 5 cm lateral to the vertebral spines. Divide the muscle horizontally between the clavicle and spine of scapula; and reflect it laterally to identify the accessory nerve and its accompanying blood vessels, the superficial branch of transverse cervical artery and vein (refer to BDC App).

Look for the suprascapular vessels and nerve, deep to trapezius muscle, towards the scapular notch.
Cut through levator scapulae muscle midway between its two attachments and clean the dorsal scapular nerve (supplying the rhomboids) and accompanying blood vessels. Identify rhomboid minor from rhomboid major muscle.

Pull the medial or inner scapular border away from the chest wall for looking at the serratus anterior muscle.
Define attachments of latissimus dorsi muscle.

ADDITIONAL FEATURES OF MUSCLES OF THE BACK

Trapezius
1 Developmentally, the trapezius is related to the sternocleidomastoid. Both of them develop from branchial arch mesoderm and are supplied by the spinal accessory nerve.
2 The principal action of the trapezius is to rotate the scapula during abduction of the arm beyond 90°. Clinically, the muscle is tested by asking the patient to shrug his shoulder against resistance.

Structures under Cover of the Trapezius
A large number of structures lies immediately under cover of the trapezius. Some of them are shown in Figs 5.5 and 5.6 and are listed below.
A. Muscles
1 Semispinalis capitis
2 Splenius capitis
3 Levator scapulae (Fig. 5.4)
4 Inferior belly of omohyoid
5 Rhomboid minor
6 Rhomboid major
7 Supraspinatus
8 Infraspinatus
9 Latissimus dorsi
10 Serratus posterior superior
B. Vessels
1 Suprascapular artery and vein
2 Superficial branch of the transverse cervical artery (superficial cervical) (Fig. 5.5) and accompanying veins
3 Deep branch of transverse cervical artery (Fig. 5.6) (dorsal scapular) and accompanying veins
C. Nerves
1 Spinal root of accessory nerve (Fig. 5.5)
2 Suprascapular nerve
3 C3, C4 nerves
4 Posterior primary rami of C2–C6 and T1–T12 pierce the muscle to become cutaneous nerves.
D. Bursa: A bursa lies over the smooth triangular area at the root of the spine of the scapula.

Latissimus Dorsi
1 This is the only muscle which connects the pelvic girdle and vertebral column to upper limb. It possesses extensive origin and narrow insertion.

Fig. 5.4: The latissimus dorsi, the levator scapulæ, the rhomboid minor and the rhomboid major muscles

Fig. 5.5: Some of the structures under cover of the right trapezius muscle
The latissimus dorsi develops in the extensor compartment of the limb. Thereafter, it migrates to its wide attachment on the trunk, taking its nerve supply (thoracodorsal nerve) along with it (latus = wide). It is also called a swimmer’s muscle.

The latissimus dorsi is tested clinically by feeling the contracting muscle in the posterior fold of the axilla after asking the patient to cough.

Competency achievement: The student should be able to:

AN 10.9 Describe the arterial anastomosis around the scapula and mention the boundaries of triangle of auscultation.

Triangle of Auscultation

Triangle of auscultation is a small triangular interval bounded medially by the lateral border of the trapezius, laterally by the medial border of the scapula, and inferiorly by the upper border of the latissimus dorsi. The floor of the triangle is formed by the 6th and 7th rib, and 6th intercostal space (ICS), and the rhomboid major. This is the only part of the back which is not covered by big muscles. Respiratory sounds of apex of lower lobe heard through a stethoscope are better heard over this triangle on each side. On the left side, the cardiac orifice of the stomach lies deep to the triangle, and in days before X-rays were discovered, the sounds of swallowed liquids were auscultated over this triangle to confirm the oesophageal tumour (Fig. 5.3a).

Lumbar Triangle of Petit

Lumbar triangle of Petit is another small triangle surrounded by muscles. It is bounded medially by the lateral border of the latissimus dorsi, laterally by the posterior border of the external oblique muscle of the abdomen, and inferiorly by the iliac crest (which forms the base). The occasional hernia at this site is called lumbar hernia (Fig. 5.4).

After completing the dissection of the back, the limb with clavicle and scapula is detached from the trunk.

DISSECTION

For detachment of the limb, muscles which need to be incised are trapezius, levator scapulae, rhomboid minor and major, serratus anterior, latissimus dorsi and sternocleidomastoid.

The sternoclavicular joint is opened to free clavicle from the sternum. Upper limb with clavicle and scapula is removed en bloc.

FACTS TO REMEMBER

- Trapezius is a shrugging muscle supplied by spinal root of XI nerve.
- Trapezius and serratus anterior cause 90°–180° of abduction at shoulder joints.

CLINICOANATOMICAL PROBLEM

A poor young adult felt multiple nodules in the region of his neck above the clavicle. A lymph node biopsy was advised from right side of his neck. A few days after the biopsy he was unable to shrug his right shoulder.

- Why was the biopsy advised?
- Why is he not able to shrug his shoulder?
**FURTHER READING**

**Questions**

1. Describe trapezius muscle under following headings:
   a. Origin
   b. Insertion
   c. Nerve supply
   d. Actions

2. Enumerate structures under cover of trapezius.

3. Describe latissimus dorsi under following headings:
   a. Origin
   b. Insertion
   c. Nerve supply

**Multiple Choice Questions**

1. Boundaries of triangle of auscultation are not formed by one of the following structures:
   a. Lateral border of trapezius
   b. Medial border of scapula
   c. Upper border of latissimus dorsi
   d. Upper border of teres major

2. Boundaries of lumbar triangle of Petit are formed by all, except:
   a. Lateral border of latissimus dorsi
   b. Posterior border of external oblique muscle of abdomen
   c. Iliac crest
   d. Quadratus lumborum

3. Trapezius is not attached to:
   a. Clavicle
   b. First rib
   c. Occiput
   d. Scapula

4. Posterior primary rami of one of the following nerves give cutaneous branch:
   a. C1
   b. C7, C8
   c. L4, 5
   d. S1

5. Which structure does not lie just deep to trapezius?
   a. Spinal accessory nerve
   b. Superficial branch of transverse cervical artery
   c. Deep branch of transverse cervical artery
   d. C3 and C4 nerves

---

**Answers**

1. d  2. d  3. b  4. d  5. c

**VIVA VOCE**

- Mark the insertion of trapezius on the scapula.
- Name structures under cover of trapezius.
- Give the attachments of latissimus dorsi muscle.
- What are the nerves supplying trapezius?
- What is the action of rhomboid major and minor muscles?
- Give the boundaries of triangle of auscultation.
- Give the boundaries of lumbar triangle of Petit.
INTRODUCTION
The shoulder or scapular region comprises structures which are closely related to and surround the shoulder joint. For a proper understanding of the region, revise some features of the scapula and the upper end of the humerus.

SURFACE LANDMARKS
1. The upper half of the humerus is covered on its anterior, lateral and posterior aspects by the deltoid muscle. This muscle is triangular in shape and forms the rounded contour of the shoulder (Fig. 6.1).

2. The skin covering the shoulder region is supplied by:
   a. The lateral supraclavicular nerve, over the upper half of the deltoid
   b. The upper lateral cutaneous nerve of the arm, over the lower half of the deltoid
   c. The dorsal rami of the upper thoracic nerves, over the back, i.e. over the scapula.

3. The superficial fascia contains (in addition to some fat and cutaneous nerves) the inferolateral part of the platysma arising from the deltoid fascia.

4. The deep fascia covering the deltoid sends numerous septa between its fasciculi. The subscapularis, supraspinatus and infraspinatus fasciae provide origin to a part of the respective muscle.

MUSCLES OF THE SCAPULAR REGION
Features
Muscles of scapular region are the deltoid (Fig. 6.2), the supraspinatus, the infraspinatus, the teres minor, the subscapularis, and the teres major. The other muscles are described in Tables 6.1 and 6.2. The deltoid is described below.

Competency achievement: The student should be able to:
AN 10.10 Describe and identify the deltoid and rotator cuff muscles. 1

DELTOID (DELTA LIKE OR TRIANGULAR)
Origin with Features
1. The anterior border and adjoining surface of the lateral one-third of the clavicle (Fig. 6.2).
2. The lateral border of the acromion process where four septa of origin are attached (Fig. 6.2).
3. Lower lip of the crest of the spine of the scapula.

Figs 6.2a and b: The origin and insertion of the deltoide muscle
The acromial part of deltoid is an example of a multipennate muscle. Many fibres arise from four septa of origin that are attached above to the acromion process. The fibres converge onto three septa of insertion which are attached to the deltoid tuberosity (Fig. 6.2).

**Insertion**
The deltoid tuberosity of the humerus where three septa of insertion are attached.

**Nerve Supply**
Axillary nerve (C5, C6).

**Actions**
1. The multipennate acromial fibres are powerful abductors of the arm at the shoulder joint from beginning to 90°.
   A multipennate arrangement allows a large number of muscle fibres to be packed into a relatively small volume. As the strength of contraction of a muscle is proportional to the number of muscle fibres present in it (and not on their length), a multipennate muscle is much stronger than other muscles having the same volume.
2. The anterior fibres are flexors and medial rotators of the arm.
3. The posterior fibres are extensors and lateral rotators of the arm.

**Structures under Cover of the Deltoid**

**Bones**
- The upper end of the humerus
- The coracoid process

**Muscles**

**Insertions of**
- Pectoralis minor on coracoid process.
- Supraspinatus, infraspinatus, and teres minor (on the greater tubercle of the humerus) (Fig. 6.3).
- Subscapularis on lesser tubercle of humerus (Fig. 6.4).
- Pectoralis major, teres major and latissimus dorsi on the intertubercular sulcus of the humerus (Fig. 6.5).

**Origin of**
- Coracobrachialis and short head of biceps brachii from the coracoid process (Fig. 6.5).
- Long head of the biceps brachii from the supraglenoid tubercle.
- Long head of the triceps brachii from the infraglenoid tubercle.
- The lateral head of the triceps brachii from the upper part of posterior surface of the humerus.

**Vessels**
- Anterior circumflex humeral
- Posterior circumflex humeral (Fig. 6.6)

**Nerve**
Axillary (Fig. 6.6).

**Joints and Ligaments**
- Shoulder joint
- Musculotendinous cuff of the shoulder (Fig. 6.7).
- Coracoacromial ligament.

**Bursae**
Subscapular, infraspinatus bursae around the shoulder joint, including the subacromial or subdeltoid bursa (Fig. 6.8).
Define the margins of the deltoid muscle covering the shoulder joint region. Reflect the part of the muscle arising from spine of scapula downwards. Separate the infraspinatus muscle from teres major and minor muscles which run from the lateral scapular border towards humerus. Axillary nerve accompanied with posterior circumflex humeral vessels lies on the deep aspect of the deltoid muscle (refer to BDC App).

Competency achievement: The student should be able to:
AN 10.13 Explain anatomical basis of injury to axillary nerve during intramuscular injections.²

Fig. 6.5: Horizontal section of the deltoid region showing arrangement of the muscles in and around the bicipital groove

Fig. 6.6: Horizontal section of the deltoid region showing the axillary nerve and vessels around the surgical neck of humerus

Fig. 6.7: Subacromial bursa in sagittal section, with the musculotendinous cuff of the shoulder
CLINICAL ANATOMY

- Intramuscular injections are often given into the deltoid. They should be given in the middle of the muscle to avoid injury to the axillary nerve (Fig. 6.9a). If injection is given in upper part of deltoid, axillary nerve may be damaged.
- The deltoid muscle is tested by asking the patient to abduct the arm against resistance applied with one hand, and feeling for the contracting muscle with the other hand (Fig. 6.9b).
- The axillary nerve may be damaged by dislocation of the shoulder or by the fracture of the surgical neck of the humerus. The effects produced are:
  a. Rounded contour of shoulder is lost; greater tubercle of humerus becomes prominent (Fig. 6.10a).
  b. Deltoid is paralysed, with loss of the power of abduction up to 90° at the shoulder.

Figs 6.9a and b: (a) Intramuscular injection being given in deltoid muscle, and (b) deltoid muscle being tested

Figs 6.10a and b: (a) Normal rounded contour is lost on the right side. Inset shows normal contour, and (b) the sensory loss (regimental badge)
c. There is sensory loss over the lower half of the deltoid in a badge-like area called regimental badge (Fig. 6.10b).

- The tendon of the supraspinatus may undergo degeneration. This can give rise to calcification and even spontaneous rupture of the tendon.
- In subacromial bursitis, pressure over the deltoid below the acromion process with the arm by the side causes pain. However, when the arm is abducted, pressure over the same point causes no pain, because the bursa disappears under the acromion process (Dawbarn’s sign). Subacromial or subdeltoid bursitis is usually secondary to inflammation of the supraspinatus tendon.

Competency achievement: The student should be able to:

AN 10.10 Describe and identify the deltoid and rotator cuff muscles.

Musculotendinous Cuff of the Shoulder or Rotator Cuff

Musculotendinous cuff of the shoulder is a fibrous sheath formed by the four flattened tendons which blend with the capsule of the shoulder joint and strengthen it. The muscles which form the cuff arise from the scapula and are inserted into the lesser and greater tubercles of the humerus. They are the subscapularis, the supraspinatus, the infraspinatus and the teres minor (Fig. 6.7). Their tendons, while crossing the shoulder joint, become flattened and blend with each other on one hand, and with the capsule of the joint on the other hand, before reaching their points of insertion.

The cuff gives strength to the capsule of the shoulder joint all around except inferiorly. This explains why dislocations of the humerus occur commonly in an anteroinferior direction. Thus rotator cuff rests on tuberosities, fused to the capsule, strengthens the capsule and steadies head of humerus.

Subacromial Bursa

Subacromial bursa is the largest bursa of the body, situated below the coracoacromial arch and the deltoid muscle. Below the bursa, there are the tendon of the supraspinatus and the greater tubercle of the humerus (Fig. 6.8).

The subacromial bursa is of great value in the abduction of the arm at the shoulder joint.

i. It protects the supraspinatus tendon against friction with the acromion process.
ii. During overhead abduction, the greater tubercle of the humerus passes under the acromion process; this is facilitated by the presence of this bursa.

INTERMUSCULAR SPACES

INTRODUCTION

The long head of triceps brachii spans the length of the arm arising from infraglenoid tubercle of scapula to the olecranon process of ulna. It lies medial to humerus. Teres minor crosses posterior aspect of the shoulder joint and origin of the long head as it passes from its origin from scapula to the humerus. The muscle is replaced by subscapularis on the anterior aspect of shoulder joint. Teres major also crosses the long head as it runs to bicapital groove for its insertion.

Thus potential spaces are formed between lateral border of scapula, medial aspect of humerus, long head of triceps brachii, teres minor or subscapularis and teres major muscles.

In the upper part, there is a quadrangular space laterally and upper triangular space medially. In the lower part is the lower triangular space. Their boundaries are as follows.

Quadrangular Space

**Boundaries**

**Superior:**

i. Subscapularis in front.
ii. Capsule of the shoulder joint. This is the loose inferior part of the capsule of the shoulder joint. In anatomical position, the capsule lies in this space. The capsule gets taut as it is used up during abduction of the shoulder joint.
iii. Inferior border of teres minor behind.

**Inferior:** Superior border of teres major.

**Medial:** Lateral border of long head of the triceps brachii.

**Lateral:** Surgical neck of the humerus.

**Contents**

i. Axillary nerve (Fig. 6.11)
ii. Posterior circumflex humeral vessels

Upper Triangular Space

**Boundaries**

**Superior:** Inferior border of teres minor.

**Lateral:** Medial border of long head of the triceps brachii.

**Inferior:** Superior border of teres major.

**Contents**

Circumflex scapular artery. It interrupts the origin of the teres minor and reaches the infraspinous fossa for anastomoses with the suprascapular artery and deep branch of transverse cervical artery.
**SCAPULAR REGION**

### Lower Triangular Space
It is diagonally opposite the upper triangular space.

**Boundaries**
- **Medial:** Lateral border of long head of the triceps brachii.
- **Lateral:** Medial border of humerus.
- **Superior:** Lower border of teres major (Fig. 6.11).

**Contents**
- i. Radial nerve
- ii. Profunda brachii vessels

### DISSECTION
The quadrangular intermuscular space is a space in between the scapular muscles. The quadrangular space is bounded by teres minor above and teres major below; by the long head of triceps muscle medially and the surgical neck of humerus laterally. The axillary nerve accompanied with posterior circumflex humeral vessels lie in this space. Identify the nerve to the teres minor muscle (Fig. 6.11) (refer to BDC App). Identify part of the capsule of the shoulder joint.

Another intermuscular space, the upper triangular space should be dissected. It is bounded by the teres minor muscle medially, long head of triceps laterally, and teres major muscle below.

Now the remaining two-thirds of deltoid muscle can be reflected towards its insertion. Identify subscapularis muscle anteriorly.

Define the attachments of infraspinatus and cut muscle at the neck of scapula and reflect it on both sides.

---

**Competency achievement:** The student should be able to:

**AN 10.13** Explain anatomical basis of injury to axillary nerve during intramuscular injections.

---

### AXILLARY OR CIRCUMFLEX NERVE
Axillary or circumflex nerve is an important nerve because it supplies the deltoid muscle which is the main abductor of the arm. Surgically, it is important, because it is commonly involved in dislocations of the shoulder and in fractures of the surgical neck of the humerus.

The axillary nerve is a smaller terminal branch of the posterior cord of the brachial plexus (C5, C6).

**Root value:** Its root value is ventral rami of cervical 5, 6 segments of spinal cord (see Fig. 4.14).
Axillary nerve courses through lower part of axilla into the quadrangular space where it terminates by dividing into two branches (Fig. 6.6).

Relations and Branches
a. In the lower part of the axilla, the nerve runs downwards behind the third part of the axillary artery. Here it lies on the subscapularis muscle. It is related medially to the radial nerve, and laterally to the coracobrachialis (see Fig. 4.9).

The nerve leaves the axilla by winding round the lower border of the subscapularis in close relation to the lowest part of the capsule of the shoulder joint where it gives a branch to the capsule of the joint and enters the quadrangular space (Fig. 6.8).
b. The nerve then passes backwards through the quadrangular space. Here it is accompanied by the posterior circumflex humeral vessels and has the following relations (Fig. 6.11).

- **Superiorly:**
  i. Subscapularis anteriorly or teres minor posteriorly.
  ii. Lowest part of the capsule of the shoulder joint.
- **Laterally:** Surgical neck of humerus.
- **Inferiorly:** Teres major.
- **Medially:** Long head of the triceps brachii.

In the quadrangular space, the nerve divides into anterior and posterior branches (Fig. 6.6).

c. The anterior branch is accompanied by the posterior circumflex humeral vessels. It winds around the surgical neck of the humerus, deep to the deltoid muscle supplying the deltoid and the skin over its anteroinferior part.
d. The posterior branch supplies the teres minor and the posterior part of the deltoid. The nerve to the teres minor bears a pseudoganglion, i.e. fibrous tissue and fat without any neurons (Fig. 6.6). The posterior branch then pierces the deep fascia at the lower part of the posterior border of the deltoid and continues as the upper lateral cutaneous nerve of the arm. Its clinical anatomy has been given on p-77.

**Competency achievement:** The student should be able to:

**AN 10.9** Describe the arterial anastomosis around the scapula and mention the boundaries of triangle of auscultation.  

**ANASTOMOSES AROUND SCAPULA**

Anastomosis Around the Body of the Scapula
The anastomosis occurs in the three fossae—subscapular, supraspinous and infraspinous. It is formed by:
a. The suprascapular artery, a branch of the thyrocervical trunk (Fig. 6.12).
b. The deep branch of the transverse cervical artery, another branch of the thyrocervical trunk.
c. The circumflex scapular artery, a branch of the subscapular artery which arises from the third part of the axillary artery.
Note that it is the anastomosis between branches of the first part of the subclavian artery and the branches of the third part of the axillary artery. These arteries also anastomose with intercostal arteries.

**Anastomosis Over the Acromion Process**

It is formed by:

a. The acromial branch of the thoracoacromial artery (2nd part of axillary).

b. The acromial branch of the suprascapular artery (1st part of subclavian).

c. The acromial branch of the posterior circumflex humeral artery (3rd part of axillary).

Note that this is the anastomosis between the first part of the subclavian artery and the branches of the second and third parts of the axillary artery (Fig. 6.12).

**Competency achievement:** The student should be able to:

AN 10.13 Explain anatomical basis of injury to axillary nerve during intramuscular injections.6

**CLINICAL ANATOMY**

The arterial anastomoses provide a collateral circulation through which blood can flow to the limb when the distal part of the subclavian artery, or the proximal part of the axillary artery is blocked (Fig. 6.12).

Fracture of middle one-third of humerus causes injury to radial nerve as it lies in lower triangular space. This results in ‘wrist drop’.

**Mnemonics**

**Suprascapular nerve and artery**

Army (artery) goes over the bridge

Navy (nerve) goes under the bridge

Artery—suprascapular

Nerve—suprascapular

Bridge—superior transverse scapular ligament.

**Rotator cuff muscles**

The SITS muscles

Clockwise from top

Supraspinatus

Infraspinatus

Teres minor

Subscapularis

**FACTS TO REMEMBER**

- Branches of axillary nerve with accompanying blood vessels pass through the quadrangular intermuscular space.
- Loose fold of capsule of shoulder joint forms upper boundary of the quadrangular intermuscular space.
- Radial nerve and profunda brachii vessels course through the lower triangular intermuscular space.
- Only circumflex scapular vessels pass through the upper triangular space.
- Long head of triceps brachii is placed between quadrangular and upper triangular spaces. Lower down it forms a boundary of lower triangular space.

**CLINICOANATOMICAL PROBLEM**

A patient came with injury on left shoulder region after an accident. He was not able to abduct his shoulder joint.

- Which nerve is injured?
- Where is the sensory loss?

**Ans:** Due to the injury to the surgical neck of humerus, the axillary nerve got damaged. Patient feels inability to abduct the shoulder joint.

The sensory loss is over the lower half of deltoid muscle and is called regimental-badge area due to injury to upper lateral cutaneous nerve of the arm, a branch of the axillary nerve.

**FURTHER READING**

  A description of an example of the value of testing muscle capacity by eccentric activity, a more sensitive clinical method of determining weakness (i.e. decrement from normal without testing against the power of the observer) than using resistance against a load (concentric activity).

  A description of the internal architecture of deltoid in relation to the discrete functions of the parts of that muscle.

**Frequently Asked Questions**

1. Describe deltoid muscle under following headings:
   a. Origin, insertion, action and nerve supply
   b. Structures under cover of deltoid
   c. Effect of paralysis of the muscle
2. Describe the boundaries and contents of quadrangular, upper and lower triangular spaces.
3. Write short notes/enumerate:
   a. Course and branches of axillary nerve
   b. Anastomoses around the body of scapula
   c. Anastomoses over the acromion process
   d. Musculotendinous cuff of shoulder/rotator cuff

**Multiple Choice Questions**

1. Skin of lateral side of arm is supplied by all, except:
   a. Lateral supraclavicular nerve
   b. Intermediate supraclavicular nerve
   c. Upper lateral cutaneous nerve of arm
   d. Lower lateral cutaneous nerve of arm
2. Which part of deltoid is multipennate?
   a. Clavicular fibres
   b. Acromial fibres
   c. Fibres from spine of scapula
   d. Whole of the muscle
3. Rotator cuff is formed by all, except:
   a. Supraspinatus
   b. Infraspinatus
   c. Teres major
   d. Subscapularis
4. Which of the following nerves has a pseudo-ganglion?
   a. Suprascapular nerve
   b. Axillary nerve
   c. Nerve to teres minor
   d. Nerve to serratus anterior
5. Boundaries of quadrangular space are not formed by:
   a. Teres minor
   b. Long head of biceps brachii
   c. Surgical neck of humerus
   d. Teres major
6. Which is not a content of lower triangular space?
   a. Profunda brachii artery
   b. Radial nerve
   c. Superior ulnar collateral artery
   d. Profunda brachii vein
7. Anastomosis around body of scapula is between:
   a. 1st part of subclavian artery and 3rd part of axillary artery
   b. 2nd part of subclavian artery and 2nd part of axillary artery
   c. 3rd part of subclavian artery and 3rd part of axillary artery
   d. 1st part of subclavian artery and 2nd part of axillary artery

**Answers**

1. b  2. b  3. c  4. c  5. b  6. c  7. a

**VIVA VOCE**

- What type of fibres are the middle fibres of deltoid muscle?
- Show the main action of deltoid muscle.
- Name the structures under cover of deltoid.
- Where is intramuscular injection given in deltoid and why?
- Name the muscles forming rotator cuff of shoulder.
- Name the boundaries of quadrangular space and give its contents.
- What structures lie in the lower triangular space?
- What does the word ‘profunda’ mean?
- Why is axillary nerve called circumflex nerve?
- Name muscles supplied by the axillary nerve.
- Name the arteries taking part in the anastomoses around scapula.
- What is the clinical importance of the anastomoses around scapula?
INTRODUCTION

The superficial fascia seen after the reflection of skin contains cutaneous nerves, cutaneous or superficial veins and lymphatics. The cutaneous nerves are the continuation of the spinal nerves and carry sympathetic fibres for supplying the sweat glands, arterioles in the dermis and arrector pilorum muscles in relation to the hair follicle. Thus, the effects of sympathetic on the skin are sudomotor (increase sweat secretion); vasomotor (narrow the arterioles of skin) and pilomotor (contract arrector pilorum muscle to make the hair erect or straight), respectively. The nerves also carry sensation of pain, touch, temperature and pressure. Superficial veins are seen along with the cutaneous nerves. These are utilised for giving intravenous transfusions, cardiac catheterisation and taking blood samples. Lymphatic vessels though important are not easily seen in ordinary dissection.

CUTANEOUS NERVES

Position

The skin of the upper limb is supplied by 15 sets of cutaneous nerves (Table 7.1). Out of these, only one set (supraclavicular) is derived from the cervical plexus, and another nerve (intercostobrachial) is derived from the second intercostal nerve. The remaining 13 sets are derived from the brachial plexus through the musculocutaneous, median, ulnar, axillary and radial nerves. Some branches arise directly from the medial cord of the plexus.

It should be noted as follows:

a. The areas of distribution of peripheral cutaneous nerves do not necessarily correspond with those of individual spinal segments (areas of the skin supplied by individual spinal segments are called dermatomes). This is so because each cutaneous nerve contains fibres from more than one ventral ramus (of a spinal nerve); and each ramus gives fibres to more than one cutaneous nerve.

b. Adjacent areas of skin supplied by different cutaneous nerves overlap each other to a considerable extent. Therefore, the area of sensory loss after damage to a nerve is much less than the area of distribution of the nerve. The anaesthetic area is surrounded by an area in which the sensations are somewhat altered.

c. In both the upper and lower limbs, the nerves of the anterior or flexor surface have a wider area of distribution than those supplying the posterior or extensor surface.

The individual cutaneous nerves, from above downwards, are described below with their root values. Figures 7.1a and b show the cutaneous nerves of the upper limb.

1. The supraclavicular nerves (C3, C4) are branches of the cervical plexus. They pierce the deep fascia in the neck, descend superficial to the clavicle, and supply:
   a. The skin of the pectoral region up to the level of the second rib.
   b. Skin covering the upper half of the deltoid.

2. The upper lateral cutaneous nerve of the arm (C5, C6) is the continuation of the posterior branch of the axillary nerve. It supplies the skin covering the lower half of the deltoid.

3. The lower lateral cutaneous nerve of the arm (C5, C6) is a branch of the radial nerve given off in the radial groove. It supplies the skin of the lower half of the lateral side of the arm.

4. The intercostobrachial nerve (T2) is the lateral cutaneous branch of the second intercostal nerve. It crosses the axilla, and supplies the skin of the

5 The medial cutaneous nerve of the arm (T1, T2) is the smallest branch of the medial cord of the brachial plexus.

6 The posterior cutaneous nerve of the arm (C5) is a branch of the radial nerve given off in the axilla. It supplies the skin of the back of the arm from the insertion of the deltoid to the olecranon process.

7 The lateral cutaneous nerve of the forearm (C5, C6) is the continuation of the musculocutaneous nerve. It pierces the deep fascia just lateral to the tendon of the biceps 2–3 cm above the bend of the elbow, and supplies the skin of the lateral side of the forearm, extending anteriorly to a small part of the ball of the thumb.

8 The medial cutaneous nerve of the forearm (C8, T1) is a branch of the medial cord of the brachial plexus. It runs along the medial side of the axillary and brachial arteries, and supplies the skin of the medial side of the forearm.

9 The posterior cutaneous nerve of the forearm (C6–C8) arises from the radial nerve, in the radial groove. It descends posterior to the lateral epicondyle and supplies the skin of the back of the forearm.

10 The median nerve gives off two sets of cutaneous branches in the hand.

a. The palmar cutaneous branch (C6–C8) arises a short distance above the wrist, lies superficial to flexor retinaculum and supplies skin over the lateral two-thirds of the palm including that over the thenar eminence (Fig. 7.1a).

b. Palmar digital branches (C6–C8) are five in number and arise in the palm. The medial two branches are common palmar digital nerves; each divides near a digital cleft to form two proper palmar digital nerves. The lateral three branches are proper palmar digital nerves for the medial and lateral sides of the thumb and for the lateral side of the index finger. The various digital branches of the median nerve supply palmar skin of the lateral 3½ digits,
the nail beds, and skin on the dorsal aspect of the distal phalanges of the same digits (Fig. 7.1b).

11 The ulnar nerve gives off three sets of cutaneous nerves in hand.

a. The palmar cutaneous branch (C7, C8) arises in the middle of the forearm and descends, crossing superficial to flexor retinaculum and supplies skin of the medial one-third of the palm.

b. The palmar digital branches of the ulnar nerve (C7, C8) are two in number. They arise from the superficial terminal branch of the ulnar nerve just distal to the pisiform bone. The medial of the two branches is a proper palmar digital nerve for the medial side of the little finger. The lateral branch is a common palmar digital nerve which divides into two proper digital nerves for supply of adjacent sides of the ring and little fingers. Thus it supplies skin of medial 1½ digits, their nail beds and skin on the dorsal aspects of distal phalanges of medial 1½ digits (Figs 7.1a and b).

c. The dorsal branch of the ulnar nerve (C7, C8) arises about 5 cm above the wrist. It descends with the main trunk of the ulnar nerve almost to the pisiform bone. Here, it passes backwards to divide into three (sometimes two) dorsal digital nerves. Typically, the region of skin supplied by the dorsal branch covers the medial half of the back of the hand, and the skin on the dorsal aspect of the medial 2½ digits (see Fig. 11.6).

12 The superficial terminal branch of the radial nerve (C6–C8) arises in front of the lateral epicondyle of the humerus. It descends through the upper two-thirds of the forearm lateral to the radial artery, and then passes posteriorly about 7 cm above the wrist. While winding round the radius it pierces the deep fascia and divides into four or five small dorsal digital nerves. In all, the superficial terminal branch supplies the skin of the lateral half of the dorsum of the hand, and the dorsal surfaces of the lateral 2½ digits including the thumb, except for the terminal portions supplied by the median nerve.

**DISSECTION**

Make one horizontal incision in the arm at its junction of upper one-third and lower two-thirds segments (see Fig. 3.2) and a vertical incision through the centre of arm and forearm till the wrist where another transverse incision is given.

Reflect the skin on either side on the front as well as on the back of the limb. Use this huge skin flap to cover the limb after the dissection.
Competency achievement: The student should be able to:

AN 13.2 Describe dermatomes of upper limb.

DERMATOMES

Definition
The area of skin supplied by one spinal segment is called a dermatome. A typical dermatome extends from the posterior median line to the anterior median line around the trunk (see Fig. 5.2). However, in the limbs, the dermatomes have migrated rather irregularly, so that the original uniform pattern is disturbed.

Embryological Basis
The early human embryo shows regular segmentation of the body. Each segment is supplied by the corresponding segmental nerve. In an adult, all structures including the skin, developed from one segment, are supplied by their original segmental nerve. The limb may be regarded as an extension of the body wall, and the segments from which they are derived can be deduced from the spinal nerves supplying them. The limb buds arise in the area of the body wall supplied by the lateral branches of anterior primary rami. The nerves to the limbs represent these branches (Fig. 7.2).

Important Features
1. The cutaneous innervation of the upper limb is derived:
   a. Mainly from segments C5–C8 and T1 of the spinal cord, and
   b. Partly from the overlapping segments from above (C3, C4) as well from below (T2, T3). The additional segments are found only at the proximal end of the limb (Fig. 7.3).
2. Since the limb bud appears on the ventrolateral aspect of the body wall, it is invariably supplied by the anterior primary rami of the spinal nerves. Posterior primary rami do not supply the limb. It is possible that the ventral and dorsal divisions of the trunks of the brachial plexus represent the anterior and posterior branches of the lateral cutaneous nerves (see Figs 4.14, 5.2 and 7.4).
3. There is varying degree of overlapping of adjoining dermatomes, so that the area of sensory loss following damage to the cord or nerve roots is always less than the area of distribution of the dermatomes (Fig. 7.5).
4. Each limb bud has a cephalic and a caudal border, known as preaxial and postaxial borders, respectively. In the upper limb, the thumb and radius lie along the
preaxial border, and the little finger and ulna along the postaxial border.

The dermatomes of the upper limb are distributed in an orderly numerical sequence (Figs 7.6a and b).

a. Along the preaxial border, by segments C3–C6 with overlapping of the dermatomes.

b. The middle three digits (index, middle and ring fingers) and the adjoining area of the palm are supplied by segment C7.

c. The postaxial border is supplied (from below upwards) by segments C8, T1, T2. There is overlapping of the dermatomes.

As the limb elongates, it rotates laterally and gets adducted and the central dermatome C7 gets pulled in such a way that these are represented only in the distal part of the limb, and are buried proximally.

On the front of the limb, areas supplied by C5 and C6 segments adjoin the areas supplied by C8, T1 and T2 segments. There is a dividing line between them, known as the ventral axial line along which C7 is buried proximally. It reaches the skin just proximal to the wrist (Fig. 7.6a).

On the back of the limb, C7 reaches the skin just proximal to the elbow. So the dorsal axial line ends more proximal to the ventral axial line. There is no overlapping across the ventral and dorsal axial lines (Fig. 7.6b).

**CLINICAL ANATOMY**

- The area of sensory loss of the skin, following injuries of the spinal cord or of the nerve roots, conforms to the dermatomes. Therefore, the segmental level of the damage to the spinal cord can be determined by examining the dermatomes for touch, pain and temperature. Note that injury to a peripheral nerve produces sensory loss corresponding to the area of distribution of that nerve.

- The spinal segments do not lie opposite the corresponding vertebrae. In estimating the position of a spinal segment in relation to the surface of the body, it is important to remember that a vertebral spine is always lower than the corresponding spinal segment. As a rough guide, it may be stated that in the cervical region, there is a difference of one segment, e.g. the 5th cervical spine lies lower than the 5th cervical spinal segment. It overlies the 6th cervical spinal segment.

**Competency achievement:** The student should be able to:

AN 13.1 Describe veins of upper limb and its lymphatic drainage.
Superficial veins of the upper limb assume importance in medical practice because these are most commonly used for intravenous injections and for withdrawing blood for testing.

**General Remarks**

1. Most of the superficial veins of the limb join together to form two large veins, cephalic (preaxial) and basilic (postaxial).
2. The superficial veins run away from pressure points. Therefore, they are absent in the palm (fist area), along the ulnar border of the forearm (supporting border) and in the back of the arm and trapezius region. This makes the course of the veins spiral, from the dorsal to the ventral surface of the limb.
3. The preaxial vein is longer than the postaxial. In other words, the preaxial vein drains into the deep (axillary) vein more proximally (at the root of the limb) than the postaxial vein which becomes deep in the middle of the arm.
4. The earlier a vein becomes deep the better, because the venous return is then assisted by muscular compression. The load of the preaxial (cephalic) vein is greatly relieved by the more efficient postaxial (basilic) vein through a short circuiting channel (the median cubital vein situated in front of the elbow) and partly also by the deep veins through a perforator vein connecting the median cubital to the deep vein.
5. The superficial veins are accompanied by cutaneous nerves and superficial lymphatics, and not by arteries. The superficial lymph nodes lie along the veins, and the deep lymph nodes along the arteries.
6. The superficial veins are best utilised for intravenous injections.

**INDIVIDUAL VEINS**

**Dorsal Venous Arch**

Dorsal venous arch lies on the dorsum of the hand (Figs 7.7a and c). Its afferents (tributaries) include:

1. Three dorsal metacarpal veins.
2. A dorsal digital vein from the medial side of the little finger.
3. A dorsal digital vein from the radial side of the index finger.
4. Two dorsal digital veins from the thumb.
5. Most of the blood from the palm courses through veins passing around the margins of the hand and also by perforating veins passing through the interosseous spaces. Pressure on the palm during gripping fails to impede the venous return due to the mode of drainage of the palm into the dorsal venous arch. The efferents of dorsal venous arch are the cephalic and basilic veins.

**Cephalic Vein**

Cephalic vein is the preaxial vein of the upper limb (cf. great saphenous vein of the lower limb).

---

**Figs 7.7a and b:** The superficial veins of the upper limb: (a) On the back, (b) on the front of the limb, and (c) schematic
It begins from the lateral end of the dorsal venous arch.
It runs upwards:
  i. Through the roof of the anatomical snuffbox.
  ii. Winds around the lateral border of the distal part of the forearm (Figs 7.7b and c).
  iii. Continues upwards in front of the elbow and along the lateral border of the biceps brachii.
  iv. Pierces the deep fascia at the lower border of the pectoralis major.
  v. Runs in the deltopectoral groove up to the infracavicular fossa.
  vi. It pierces the clavipectoral fascia and joins the axillary vein (see Fig. 3.12).
At the elbow, the greater part of its blood is drained into the basilic vein through the median cubital vein, and partly also into the deep veins through the perforator vein.
It is accompanied by the lateral cutaneous nerve of the forearm, and the terminal part of the radial nerve.
An accessory cephalic vein is sometimes present. It ends by joining the cephalic vein near the elbow.

Basilic Vein
Basilic vein is the postaxial vein of the upper limb (cf. short saphenous vein of the lower limb).
It begins from the medial end of the dorsal venous arch (Figs 7.7a and c).
It runs upwards:
  i. Along the back of the medial border of the forearm,
  ii. Winds around this border near the elbow,
  iii. Continues upwards in front of the elbow (medial epicondyle) and along the medial margin of the biceps brachii up to the middle of the arm, where
    • It pierces the deep fascia, and
    • Runs along the medial side of the brachial artery up to the lower border of teres major where it becomes the axillary vein.
About 2.5 cm above the medial epicondyle of the humerus, it is joined by the median cubital vein.
It is accompanied by the posterior branch of the medial cutaneous nerve of the forearm and the terminal part of the dorsal branch of the ulnar nerve.

Median Cubital Vein
Medial cubital vein is a large communicating vein which shunts blood from the cephalic to the basilic vein (Fig. 7.7a).
It begins from the cephalic vein 2.5 cm below the bend of the elbow, runs obliquely upward and medially, and ends in the basilic vein 2.5 cm above the medial epicondyle. It is separated from the brachial artery by the bicipital aponeurosis.
It may receive tributaries from the front of the forearm (median vein of the forearm) and is connected to the deep veins through a perforator vein which pierces the bicipital aponeurosis. The perforator vein fixes the median cubital vein and thus makes it ideal for intravenous injections.

Median Vein of the Forearm
Median vein of the forearm begins from the palmar venous network, and ends in any one of the veins in front of the elbow mostly in median cubital vein.

Deep Veins
Deep veins start as small venae comitantes running on each side of digital veins. These continue proximally as superficial and deep palmar arches.
Then, these course proximally to continue as venae comitantes of radial and ulnar arteries; which further join to form the brachial veins.
Brachial veins lie on each side of brachial artery. These join the axillary vein at the lower border of teres major. Axillary vein is described in axilla (see chapter 4).

Competency achievement: The student should be able to:

AN 11.3 Describe the anatomical basis of venepuncture of cubital veins.³
Along the course of these lymph vessels, there are groups of lymph nodes.

Lymph vessels are difficult to see and special techniques are required for their visualisation.

Lymph nodes are small bean-like structures that are usually present in groups. These are not normally palpable in the living subject.

However, they often become enlarged in disease, particularly by infection or by malignancy in the area from which they receive lymph. They then become palpable and examination of these nodes provides valuable information regarding the presence and spread of disease.

It is, therefore, of importance for the medical student to know the lymphatic drainage of the different parts of the body.

Lymph Nodes

The main lymph nodes of the upper limb are the axillary lymph nodes. These comprise anterior, posterior, lateral, central and apical groups. These have been described in Chapter 4 (see Fig. 4.11). Other nodes are as follows:

1. The infraclavicular nodes lie in or on the clavipectoral fascia along the cephalic vein. They drain the upper part of the breast, and the thumb with its web.
2. The deltopectoral node lies in the deltopectoral groove along the cephalic vein. It is a displaced node of the infraclavicular set, and drains similar structures.
3. The superficial cubital or supratrochlear nodes lie just above the medial epicondyle along the basilic vein. They drain the ulnar side of the hand and forearm.
4. A few other deep lymph nodes lie in the following regions:
   i. Along the medial side of the brachial artery.
   ii. At the bifurcation of the brachial artery (deep cubital lymph node).
   iii. Occasionally along the arteries of the forearm.

Lymphatics

Superficial Lymphatics

Superficial lymphatics are much more numerous than the deep lymphatics. They collect lymph from the skin and subcutaneous tissues. Most of them ultimately drain into the axillary nodes, except for:

i. A few vessels from the medial side of the forearm which drain into the superficial cubital nodes.
ii. A few vessels from the lateral side of the forearm which drain into the deltopectoral or infraclavicular nodes.

The dense palmar plexus drains mostly into the lymph vessels onto the dorsum of the hand, where these continue with the vessels of the forearm. Lymph vessels of the back of forearm and arm curve round their medial...
and lateral surfaces and ascend up to reach the floor of the axilla. Thus, there is a vertical area of lymph shed in the middle of back of forearm and arm (Figs 7.10a and b).

**Deep Lymphatics**

Deep lymphatics are much less numerous than the superficial lymphatics. They drain structures lying deep to the deep fascia. They run along the main blood vessels of the limb, and end in the axillary nodes. Some of the lymph may pass through the deep lymph nodes present along the axillary vein as mentioned above.

---

**CLINICAL ANATOMY**

- Inflammation of lymph vessels is known as lymphangitis. In acute lymphangitis, the vessels may be seen through the skin as red, tender (painful to touch) streaks (Fig. 7.11).
- Inflammation of lymph nodes is called lymphadenitis. It may be acute or chronic. The nodes enlarge and become palpable and painful (Fig. 7.12).
- Obstruction to lymph vessels can result in accumulation of tissue fluid in areas of drainage. This is called lymphoedema. This may be caused by carcinoma because of surgical removal of lymph nodes (Fig. 7.13b).
- Pain along the medial side of upper arm is due to pressure on the intercostobrachial nerve by enlarged central group of axillary lymph nodes.
FACTS TO REMEMBER

- Ventral axial line ends close to wrist joint, while dorsal axial line ends close to elbow joint.
- Dermatome is an area of skin supplied by single spinal segment through a pair of right and left spinal nerves with both of its dorsal and ventral rami.
- There is no overlapping of the nerve supply across the axial lines.
- Cephalic vein at its beginning in the ‘anatomical snuffbox’ and median cubital vein near the elbow are the veins of choice for intravenous infusions.
- Median cubital vein is protected from the brachial artery by the bicipital aponeurosis.

CLINICOANATOMICAL PROBLEMS

Case 1
A patient came dehydrated with history of diarrhoea and vomiting. He needed intravenous fluids.
- Which vein is most convenient for intravenous infusion of glucose and why?
- How does one make the vein prominent?

Ans: Median cubital vein is most conveniently placed anterior to the elbow joint.
- Deep to the vein is bicipital aponeurosis which mostly prevents the needle from entering into the underlying brachial artery.
- The vein is made prominent by tying a tourniquet on the arm or by keeping one’s hand tightly around the arm, and asking the patient to do flexion and extension of elbow in a fast mode.
- Due to this exercise, the venous return gets increased, but is prevented from drainage into deeper veins due to compression applied to the arm. This makes the superficial veins prominent.

Case 2
A female patient of 60 years felt two nodular swellings in her right axilla.
- What parts of the body have to be examined?
- What is the probable diagnosis of these swellings?

Ans: The parts to be examined are both the mammary glands for any tumour, axilla of both sides for more palpable lymph nodes, supraclavicular and infraclavicular lymph nodes, examination of abdomen and pelvis for any spread in the liver or ovary.
- On examination of her right breast, there was a firm mass which she did not feel.
- Since there was a firm painless mass in the upper lateral quadrant of her right breast, the diagnosis would be secondary (metastasis) in the axillary lymph node from primary breast tumour. It would be confirmed by fine needle aspiration cytology and other tests.

FURTHER READING

1. Write short notes/enumerate:
   a. Nerve supply of dorsum of hand
   b. Nerve supply nail beds of all 5 digits
   c. Median cubital vein
   d. Ventral axial line

2. Describe the beginning, course and termination of basilic vein.

3. Describe the lymphatic drainage of upper limb.
   Enumerate the groups of lymph nodes of the axilla.

**Multiple Choice Questions**

1. Skin of nail bed of ring finger is supplied by:
   a. Lateral half by median, medial half by ulnar
   b. Medial half by median, lateral half by radial
   c. Whole by median nerve
   d. Whole by ulnar nerve

2. Skin of anterior, medial and lateral sides of arm is supplied by all, except:
   a. Medial cutaneous nerve of arm
   b. Lateral supraclavicular nerve
   c. Posterior cutaneous nerve of arm
   d. Intercostobrachial nerve

3. Ventral axial line extends till:
   a. Wrist joint
   b. Elbow joint
   c. Middle of forearm
   d. Middle of arm

4. Cephalic vein drains into axillary vein:
   a. In lower part of arm
   b. In upper part of arm
   c. In the forearm
   d. In infraclavicular fossa

5. Lymph shed lies on the:
   a. Lateral side of arm
   b. Medial side of arm
   c. Anterior aspect of arm
   d. Posterior aspect of arm

6. Spinal segments T1–T6 lie opposite to:
   a. Spines of 1–4 thoracic vertebrae
   b. Spines of 1–6 thoracic vertebrae
   c. Spines of 2–7 thoracic vertebrae
   d. Spines of 2–8 thoracic vertebrae

- Where does dorsal axial line end in UL?
- Which are the commonly used veins for venipuncture?
INTRODUCTION

The arm extends from the shoulder joint till the elbow joint. The skeleton of the arm is a ‘solo’ bone, the humerus. Medial and lateral intermuscular septa divide the arm into an anterior or flexor compartment and a posterior or extensor compartment, to give each compartment its individuality and freedom of action. Since the structures in the front of arm continue across the elbow joint into the cubital fossa, the cubital fossa is also included in this chapter. The arm is called brachium, so most of the structures in this chapter are named accordingly, like brachialis, coracobrachialis and brachial artery.

SURFACE LANDMARKS

The following landmarks can be felt in the living subject.

1. The greater tubercle of the humerus is the most lateral bony point in the shoulder region. It can be felt just below the acromion process, deep to the deltoid when the arm is by the side of the trunk (Fig. 8.1).

2. The shaft of the humerus is felt only indistinctly because it is surrounded by muscles in its upper half. In the lower half, the humerus is covered anteriorly by the biceps brachii and brachialis, and posteriorly by the triceps brachii.

3. The medial epicondyle of the humerus is a prominent bony projection on the medial side of the elbow. It is best seen and felt in a mid-flexed elbow.

4. The lateral epicondyle of the humerus is less prominent than the medial. It can be felt in the upper part of the depression on the posterolateral aspect of the elbow in the extended position of the forearm.

5. The medial and lateral supracondylar ridges are better defined in the lower portions of the medial and lateral borders of the humerus. They can be felt in the lower one-fourth of the arm as upward continuations of the epicondyles.

6. The deltoid forms the rounded contour of the shoulder. The apex of the muscle is attached to the deltoid tuberosity located at the middle of the anterolateral surface of the humerus.

7. The coracobrachialis forms an inconspicuous rounded ridge in the upper part of the medial side of the arm. Pulsations of the brachial artery can be felt in the depression behind it.

8. The biceps brachii muscle is overlapped above by the pectoralis major and by the deltoid. Below these muscles, the biceps forms a conspicuous elevation on the front of the arm. Upon flexing the elbow, the contracting muscle becomes still more prominent. The tendon of the biceps can be felt in front of the arm.
elbow. The tendon is a guide to the brachial artery which lies on its medial side.

9 The *brachial artery* can be felt in front of the elbow joint just medial to the tendon of the biceps brachii. Brachial pulsations are used for recording the blood pressure.

10 The *ulnar nerve* can be rolled by the palpating finger behind the medial epicondyle of the humerus. During leprosy, this nerve becomes thick and enlarged.

11 The superficial cubital veins can be made more prominent by applying tight pressure round the arm and then contracting the forearm muscles by clenching and releasing the fist a few times. The cephalic vein runs upwards along the lateral border of the biceps. The basilic vein can be seen along the lower half of the medial border of the biceps. The cephalic and basilic veins are connected together in front of the elbow by the median cubital vein which runs obliquely upwards and medially.

### COMPARTMENTS OF THE ARM

The arm is divided into anterior and posterior compartments by extension of deep fascia which are called the *medial and lateral intermuscular septa* (Fig. 8.2). These septa provide additional surface for the attachment of muscles. They also form planes along which nerves and blood vessels travel. The septa are well defined only in the lower half of the arm and are attached to the medial and lateral borders and supracondylar ridges of the humerus. The medial septum is pierced by the ulnar nerve and the superior ulnar collateral artery; the lateral septum is pierced by the radial nerve and radial collateral artery or the anterior descending branch of the profunda brachii artery (Fig. 8.7).

Two additional septa are present in the anterior compartment of the arm. The *transverse septum* separates the biceps from the brachialis and encloses the musculocutaneous nerve. The *anteroposterior septum* separates the brachialis from the muscles attached to the lateral supracondylar ridge; it encloses the radial nerve and the anterior descending branch of the profunda brachii artery.

---

**ANTERIOR COMPARTMENT**

**MUSCLES**

Muscules of the anterior compartment of the arm are the coracobrachialis, the biceps brachii and the brachialis. They are described in Tables 8.1 and 8.2.

**Morphological Importance of Coracobrachialis**

Morphologically, the muscle is very important for following reasons.

The coracobrachialis represents the medial compartment, which is so well developed in the thigh.

In some animals, it is a tricipital muscle. In human, the upper two heads have fused and musculocutaneous nerve passes between the two, and the lowest third head has disappeared. Persistence of the lower head in human is associated with the presence of ‘ligament of Struthers’, which is a fibrous band extending from the trochlear spine to the medial epicondyle of the humerus, to which the third head of the coracobrachialis is inserted, and from the lower part of which the pronator teres muscle takes origin. Beneath the ligament pass the median nerve or brachial artery or both.

The front or anterior compartment of the arm is homologous with flexor and medial compartments of the thigh. The flexor compartment of thigh lies posteriorly because the lower limb bud rotates medially.

---

**NERVES**

**Musculocutaneous Nerve**

The musculocutaneous nerve is the main nerve of the front of the arm, and continues below the elbow as the lateral cutaneous nerve of the forearm (see Fig. 7.1a).

It is a branch of the lateral cord of the brachial plexus, arising at the lower border of the pectoralis minor (see Fig. 4.14) in the axilla.

</tbody>
</table>

**Root Value**
The root value of musculocutaneous nerve is ventral rami of C5–C7 segments of spinal cord.

**Origin, Course and Termination**
Musculocutaneous nerve arises from the lateral cord of brachial plexus in the lower part of the axilla. It accompanies the third part of the axillary artery. It then enters the front of arm, where it pierces coracobrachialis muscle.

Musculocutaneous nerve runs downwards and laterally between biceps brachii and brachialis muscles to reach the lateral side of the tendon of biceps brachii. It terminates by continuing as the lateral cutaneous nerve of forearm 2 cm above the bend of the elbow (Fig. 8.6).

**Relations**
*In the lower part of the axilla:* It accompanies the third part of the axillary artery and has the following relations.

- **Anteriorly:** Pectoralis major.
- **Posteriorly:** Subscapularis.
- **Medially:** Axillary artery and lateral root of the median nerve (see Fig. 4.9).
- **Laterally:** Coracobrachialis (see Fig. 4.9).

Musculocutaneous nerve leaves the axilla, and enters the front of the arm by piercing the coracobrachialis (Fig. 8.6).

*In the arm:* It runs downward and laterally between the biceps brachii and brachialis to reach the lateral side of the tendon of the biceps. It ends by piercing the fascia 2 cm above the bend of the forearm.
**Fig. 8.3a:** Short head of biceps brachii and coacobraclialis muscles

**Fig. 8.3b:** The biceps brachii muscle in extended elbow

**Fig. 8.3c:** Intracapsular course of long head of biceps brachii muscle
**Branches and Distribution**

*Muscular branches:* It supplies the following muscles of the front of the arm.
1. Coracobrachialis
2. Biceps brachii, long and short heads
3. Brachialis (Figs 8.6 and 8.7).

*Cutaneous branches:* Through the lateral cutaneous nerve of the forearm, it supplies the skin of the lateral side of the forearm from the elbow to the wrist including the ball of the thumb (see Fig. 7.1a).

*Articular branches:* 
1. The elbow joint through its branch to the brachialis.
2. The shoulder joint through a separate branch which enters the humerus along with its nutrient artery.

*Communicating branches:* The musculocutaneous nerve through lateral cutaneous nerve of forearm communicates with the neighbouring nerves, namely the superficial branch of the radial nerve, the posterior cutaneous nerve of the forearm, and the palmar cutaneous branch of the median nerve.
Median Nerve

Median nerve is closely related to the brachial artery throughout its course in the arm (Fig. 8.9).

In the upper part, it is lateral to the artery; in the middle of the arm, it crosses the artery from lateral to the medial side; and remains on the medial side of the artery right up to the elbow.

In the arm, the median nerve gives off a branch to the pronator teres just above the elbow and vascular branches to the brachial artery.

An articular branch to the elbow joint arises at the elbow.

Ulnar Nerve

Ulnar nerve runs on the medial side of the brachial artery up to the level of insertion of the coracobrachialis, where it pierces the medial intermuscular septum and enters the posterior compartment of the arm. It is accompanied by the superior ulnar collateral vessels.

At the elbow, it passes behind the medial epicondyle where it can be palpated with a finger (Fig. 8.13a).

Radial Nerve

At the beginning of the brachial artery, the radial nerve lies posterior to the artery (see Fig. 4.9). Soon the nerve leaves the artery by entering the radial (spiral) groove on the back of the arm where it is accompanied by the profunda brachii artery (Fig. 8.13a).

In the lower part of the arm, the nerve appears again on the front of the arm where it lies between the brachialis (medially); and the brachioradialis and extensor carpi radialis longus (laterally) (Fig. 8.17). Its branches will be discussed with the back of the arm.

DISSECTION

Make an incision in the middle of deep fascia of the upper arm right down up to the elbow joint. Reflect the flaps sideways.

The most prominent muscle seen is the biceps brachii. Deep to this, another muscle called brachialis is seen easily. In the fascial septum between the two muscles lies the musculocutaneous nerve (a branch of the lateral cord of brachial plexus). Trace the tendinous long head of biceps arising from the supraglenoid tubercle and the short head arising from the tip of the coracoid process of scapula. Identify coracobrachialis muscle on the medial side of biceps brachii. This muscle is easily identified as it is pierced by musculocutaneous nerve. Clean the branches of the nerve supplying all the three muscles dissected (refer to BDC App).

CLINICAL ANATOMY

Physician holds the patient’s wrist firmly, not letting it move. Patient is requested to flex the elbow against the resistance offered by physician’s hand. One can see and palpate hardening biceps brachii muscle (Fig. 8.8).
Biceps reflex: The musculocutaneous nerve is tested by biceps reflex. Tap the tendon of biceps with forearm pronated and partially extended at the elbow. Normal reflex is jerk-like flexion of elbow joint.

**Competency achievement:** The student should be able to:
**AN 11.2** Identify and describe origin, course, relations, branches (or tributaries), and termination of important nerves and vessels in the arm.

### BRACHIAL ARTERY

**Features**

Brachial artery is the continuation of the axillary artery. It extends from the lower border of the teres major muscle to a point in front of the elbow, at the level of the neck of the radius, just medial to the tendon of the biceps brachii.

**Beginning, Course and Termination**

Brachial artery begins at the lower border of the teres major muscle as the continuation of the axillary artery. It runs downwards and laterally in the front of the arm and crosses the elbow joint. It ends at the level of the neck of the radius in the cubital fossa by dividing into its two terminal branches, the radial and ulnar arteries.

**Relations**

1. It runs downwards and laterally, from the medial side of the arm to the front of the elbow.
2. It is superficial throughout its extent and is accompanied by two venae comitantes.
3. Anteriorly, in the middle of the arm, it is crossed by the median nerve from the lateral to the medial side; and in front of the elbow, it is covered by the bicipital aponeurosis and the median cubital vein (Fig. 8.9).
4. Posteriorly, it is related to:
   i. The triceps brachii
   ii. The radial nerve and the profunda brachii artery.
5. Medially, in the upper part, it is related to the ulnar nerve and the basilic vein, and in the lower part to the median nerve (Figs 8.9a and b).

**Figs 8.9a and b:** The course and relations of the brachial artery
Laterally, it is related to the coracobrachialis, the biceps brachii and the median nerve in its upper part; and to the tendon of the biceps brachii at the elbow (Figs 8.9a and b).

At the elbow, the structures from the medial to the lateral side are:

i. Median nerve
ii. Brachial artery
iii. Biceps brachii tendon
iv. Radial nerve on a deeper plane (MBBR).

Branches

1. Unnamed muscular branches.
2. The profunda brachii artery arises just below the teres major and accompanies the radial nerve.
3. The superior ulnar collateral branch arises in the upper part of the arm and accompanies the ulnar nerve (Figs 8.10a and b).
4. A nutrient artery is given off to the humerus.
5. The inferior ulnar collateral (or supratrochlear) branch arises in the lower part and takes part in the anastomoses around the elbow joint.
6. The artery ends by dividing into two terminal branches, the radial and ulnar arteries.

Anastomoses around the Elbow Joint

Anastomoses around the elbow joint link the brachial artery with the upper ends of the radial and ulnar arteries. They supply the ligaments and bones of the joint. The anastomoses can be subdivided into the following parts.

In front of the lateral epicondyle of the humerus, the anterior descending (radial collateral) branch of the profunda brachii anastomoses with the radial recurrent branch of the radial artery (Figs 8.10a and b).

Behind the lateral epicondyle of the humerus, the posterior descending branch of the profunda brachii artery (middle collateral) anastomoses with the interosseous recurrent branch of the posterior interosseous artery.

In front of the medial epicondyle of the humerus, the inferior ulnar collateral branch of the brachial artery anastomoses with the anterior ulnar recurrent branch of the ulnar artery.

Behind the medial epicondyle of the humerus, the superior ulnar collateral branch of the brachial artery anastomoses with the posterior ulnar recurrent branch of the ulnar artery.

DISSECTION

Dissect the brachial artery as it lies on the medial side of the upper part of the arm medial to median nerve and lateral to ulnar nerve (Figs 8.9a and b).
In the lower half of the upper arm, the brachial artery is seen lateral to the median nerve as the nerve crosses the brachial artery from lateral to medial side. Note that the median nerve and brachial artery are forming together a neurovascular bundle (refer to BDC App).

Ulnar nerve accompanied by the superior ulnar collateral branch of the brachial artery will be dissected later as it reaches the posterior (extensor) compartment of the upper arm after piercing the medial intermuscular septum (refer to BDC App).

Look for the radial nerve on the posterior aspect of artery before it enters the radial groove.

Clean the branches of brachial artery and identify other arteries which take part in the arterial anastomoses around the elbow joint.

**CLINICAL ANATOMY**

- Brachial pulsations are felt or auscultated in front of the elbow just medial to the tendon of biceps for recording the blood pressure (Fig. 8.11). Figure 8.12 shows other palpable arteries.
- Although the brachial artery can be compressed anywhere along its course, it can be compressed most favourably in the middle of the arm, where it lies on the tendon of the coracobrachialis.
- Blood for blood gas analysis is collected from brachial artery.

**Changes at the Level of Insertion of Coracobrachialis**

1. **Bone:** The circular shaft becomes triangular below this level.
2. **Fascial septa:** The medial and lateral intermuscular septa become better defined from this level down (Fig. 8.5).
3. **Muscles:**
   i. Deltoid and coracobrachialis are inserted at this level (Fig. 8.3a).
   ii. Upper end of origin of brachialis.
   iii. Upper end of origin of the medial head of triceps brachii.
4. **Arteries:**
   i. The brachial artery passes from the medial side of the arm to its anterior aspect.
   ii. The profunda brachii artery runs in the spiral groove and divides into its anterior descending/radial collateral artery and posterior descending/middle collateral branches (Fig. 8.9).
   iii. The superior ulnar collateral artery originates from the brachial artery, and pierces the medial intermuscular septum along with the ulnar nerve.
   iv. The nutrient artery of the humerus enters the bone.
5. **Veins:**
   i. The basilic vein pierces the deep fascia (Fig. 8.13b).
   ii. Two venae comitantes of the brachial artery may unite to form one brachial vein.
6. **Nerves:**
   i. The median nerve crosses the brachial artery from the lateral to the medial side (Fig. 8.9).
ii. The ulnar nerve pierces the medial intermuscular septum with the superior ulnar collateral artery and goes to the posterior compartment (Fig. 8.9).

iii. The radial nerve pierces the lateral intermuscular septum with the anterior descending (radial collateral) branch of the profunda brachii artery and passes from the posterior to the anterior compartment (Fig. 8.13a).

iv. The medial cutaneous nerve of the arm pierces the deep fascia (Fig. 8.13b).

v. The medial cutaneous nerve of the forearm pierces the deep fascia (Fig. 8.13b).

**Competency achievement:** The student should be able to:

**AN 11.5** Identify and describe boundaries and contents of cubital fossa.

---

**CUBITAL FOSSA**

**Features**

Cubital (Latin *cubitus*, elbow) fossa is a triangular hollow situated on the front of the elbow. (It is homologous with the popliteal fossa of the lower limb situated on the back of the knee.)

**Boundaries**

- Laterally — Medial border of the brachioradialis (Fig. 8.14).
- Medially — Lateral border of the pronator teres.
- Base — It is directed upwards, and is represented by an imaginary line joining the *front* of two epicondyles of the humerus.

---

**Figs 8.13a and b:** Changes in positions of nerve, veins and arteries

**Fig. 8.14:** Boundaries of the right cubital fossa
Apex — It is directed downwards, and is formed by the area where brachioradialis crosses the pronator teres muscle.

**Roof**

The roof of the cubital fossa (Fig. 8.15) is formed by:

a. Skin
b. Superficial fascia containing the median cubital vein joining the cephalic and basilic veins. The lateral cutaneous nerve of the forearm lies along with cephalic vein and the medial cutaneous nerve of the forearm along with basilic vein.
c. Deep fascia
d. Bicipital aponeurosis

**Floor**

It is formed by:

i. Brachialis (Figs 8.16a and b)
ii. Supinator surrounding the upper part of radius

**Contents**

The fossa is actually very narrow. The contents described are seen after retracting the boundaries. From medial to the lateral side, the contents are as follows:

1. **The median nerve:** It gives branches to flexor carpi radialis, palmaris longus, flexor digitorum superficialis and leaves the fossa by passing between the two heads of pronator teres (Fig. 8.18).

2. The termination of the brachial artery, and the beginning of the radial and ulnar arteries lie in the fossa. The radial artery is smaller and more superficial than the ulnar artery. It gives off the radial recurrent branch.
The radial nerve: It descends medial to lateral epicondyle to enter cubital fossa. In the fossa, it gives off the posterior interosseous nerve or deep branch of the radial nerve which gives branches to extensor capri radialis brevis and supinator. Then it leaves the fossa by piercing the supinator muscle (Fig. 8.18). The remaining superficial branch runs in the front of forearm for some distance.

**DISSECTION**

Identify the structures (see text) present in the roof of a shallow cubital fossa located on the front of the elbow. Separate the lateral and medial boundaries formed respectively by the brachioradialis and pronator teres muscles (Figs 8.14 and 8.19). Clean the contents:

i. Median nerve on the medial side of brachial artery.
ii. Terminal part of brachial artery bifurcating into radial and ulnar arteries (refer to BDC App).
iii. The tendon of biceps brachii muscle between the brachial artery and radial nerve.
iv. The radial nerve on a deeper plane on the lateral side of biceps tendon.

Identify brachialis and supinator muscles, forming the floor of cubital fossa.

**CLINICAL ANATOMY**

- The cubital region is important for the following reasons:
  a. The median cubital vein is often the vein of choice for intravenous injections (see Fig. 7.8). It is used for introducing cardiac catheters to get sample of blood from various chambers of heart.
  b. The blood pressure is universally recorded by auscultating the brachial artery in front of the elbow (Fig. 8.11).
- The anatomy of the cubital fossa is useful while dealing with the fracture around the elbow, like the supracondylar fracture of the humerus.

**POSTERIOR COMPARTMENT**

**Features**

The region contains the triceps muscle, the radial nerve and the profunda brachii artery. The nerve and artery run through the muscle. The ulnar nerve runs through the lower part of this compartment.

*Competency achievement: The student should be able to:*

**AN 11.1** Describe and demonstrate muscle groups of upper arm with emphasis on biceps and triceps brachii.

Biceps has been described in Tables 8.1 and 8.2.*/
TRICEPS BRACHII MUSCLE

Origin
Triceps brachii muscle arises by the following three heads (Figs 8.20a and b).
1. The long head arises from the infraglenoid tubercle of the scapula; it is the longest of the three heads (Fig. 8.21).
2. The lateral head arises from an oblique ridge on the upper part of the posterior surface of the humerus, corresponding to the lateral lip of the radial (spiral) groove (Fig. 8.20a and b).
3. The medial head arises from a large triangular area on the posterior surface of the humerus below the radial groove, as well as from the medial and lateral intermuscular septa. At the level of the radial groove, the medial head is medial to the lateral head (see Figs 2.14a and b).

Insertion
The long and lateral heads converge and fuse to form a superficial flattened tendon which covers the medial head and are inserted into the posterior part of the superior surface of the olecranon process (Fig. 8.20). The medial head is inserted partly into the superficial tendon, and partly into the olecranon process. Although the medial head is separated from the capsule of the elbow joint by a small bursa, a few of its fibres are inserted into this part of the capsule. This prevents nipping of the capsule during extension of the arm. These fibres are referred to as the articularis cubiti, or as the subanconeus.

Nerve Supply
Each head receives a separate branch from the radial nerve (C7, C8). The branches arise in the axilla and in the radial groove.

Actions
The triceps is a powerful active extensor of the elbow. The long head causes extension and adduction of arm at shoulder joint. It supports the head of the humerus in the abducted position of the arm. Gravity extends the elbow passively.

Electromyography has shown that the medial head of the triceps is active in all forms of extension, and the actions of the long and lateral heads are minimal, except when acting against resistance.
DISSECTION

Reflect the skin of back of arm to view the triceps brachii muscle. Define its attachments and separate the long head of the muscle from its lateral head.

Radial nerve will be seen passing between the long head of triceps and medial border of the humerus. Note the continuity of radial nerve up to axilla. Carefully cut through the lateral head of triceps to expose radial nerve along with profunda brachii vessels. Note that the radial nerve lies in the radial groove, on the back of humerus, passing between the lateral head of triceps above and its medial head below. In the lower part of arm, the radial nerve lies on the front of elbow just lateral to the brachialis, dividing into two terminal branches in the cubital fossa (refer to BDC App).

The ulnar nerve (which was seen in the anterior compartment of arm till its middle) pierces the medial intermuscular septum with its accompanying vessels, reaches the back of elbow and may easily be palpated on the back of medial epicondyle of humerus.

CLINICAL ANATOMY

- In radial nerve injuries in the arm, the triceps brachii usually escapes complete paralysis because the two nerves supplying it, arise in the axilla.
- Physician holds the flexed forearm firmly. Patient is requested to extend his elbow against the resistance of the physician's hand. The contracting triceps brachii is felt (Fig. 8.22).

RADIAL NERVE OR MUSCULOSPIRAL NERVE

Radial nerve is the largest branch of the posterior cord of the brachial plexus with a root value of C5–C8 and T1 (see Fig. 4.14).

Origin, Course and Termination

Radial nerve is given off from the posterior cord in the lower part of axilla.
1. It runs behind third part of axillary artery (see Figs 4.7c and d).
2. In the arm, it lies behind the brachial artery (Fig. 8.9a).
3. Leaves the brachial artery to enter the lower triangular space to reach the oblique radial sulcus on the back of humerus (Fig. 8.13a).
4. The nerve reaches the lateral side of arm 5 cm below deltoid tuberosity, pierces lateral intermuscular septum to enter the anterior compartment of arm on its lateral aspect (Fig. 8.13a).
5. It descends down medial to the lateral epicondyle into cubital fossa.

Radial nerve terminates by dividing into a superficial and a deep branch (posterior interosseous nerve) just below the level of lateral epicondyle. These are seen in the cubital fossa (Fig. 8.18).
Relations

a. In the lower part of the axilla, radial nerve passes downwards and has the following relations.
   Anteriorly: Third part of the axillary artery (see Fig. 4.8).
   Posteriorly: Subscapularis, latissimus dorsi and teres major.
   Laterally: Axillary nerve and coracobrachialis.
   Medially: Axillary vein (see Fig. 4.9).

b. In the upper part of the arm, it continues behind the brachial artery, and passes posterolaterally (with the profunda brachii vessels) through the lower triangular space, below the teres major, and between the long head of the triceps brachii and the humerus.
   It then enters the radial groove with the profunda vessels (see Fig. 6.11).

c. In the radial groove, the nerve runs downwards and laterally between the lateral and medial heads of the triceps brachii, in contact with the humerus (Fig. 8.13a).
   At the lower end of the groove, 5 cm below the deltoid tuberosity, the nerve pierces the lateral intermuscular septum and passes into the anterior compartment of the arm (Fig. 8.17) to reach the cubital fossa where it ends by dividing into superficial and deep branches.

Branches and Distribution

Various branches of radial nerve are shown in Figs 8.23a–c.

Figs 8.23a and b: Distribution of right radial nerve
Muscular

1. Before entering the spiral groove, radial nerve supplies the long and medial heads of the triceps brachii.
2. In the spiral groove, it supplies the lateral and medial heads of the triceps brachii and the anconeus.
3. Below the radial groove, on the front of the arm, it supplies the brachialis with proprioceptive fibres. The brachioradialis and extensor carpi radialis longus are supplied with motor fibres (Fig. 8.23a).

Cutaneous Branches

1. In the axilla, radial nerve gives off the posterior cutaneous nerve of the arm which supplies the skin on the back of the arm (see Fig. 7.1b).
2. In the radial groove, the radial nerve gives off the lower lateral cutaneous nerves of the arm and the posterior cutaneous nerve of the forearm.

Articular branches: The articular branches near the elbow supply the elbow joint.

Competency achievement: The student should be able to:
AN 11.4 Describe the anatomical basis of Saturday night paralysis.7
AN 12.13 Describe the anatomical basis of wrist drop.8

CLINICAL ANATOMY

- The radial nerve is very commonly damaged in the region of the radial (spiral) groove. The common causes of injury are as follows.
a. Sleeping in an armchair with the limb hanging by the side of the chair (Saturday night palsy),

or even the pressure of the crutch (crutch paralysis) (Figs 8.24a and b).

b. Fractures of the shaft of the humerus. This results in the weakness and loss of power of extension at the wrist (wrist drop) (Fig. 8.25) and sensory loss over a narrow strip on the back of forearm, and on the lateral side of the dorsum of the hand (Fig. 8.26).

- Wrist drop is quite disabling, because the patient cannot grip any object firmly in the hand without the synergistic action of the extensors.
Mnemonics

Cubital fossa contents MBBR
From medial to lateral:
- Median nerve
- Brachial artery
- Tendon of Biceps
- Radial nerve

Biceps brachii muscle: Origins
“You walk shorter to a street corner. You ride longer on a superhighway”
Short head originates from coracoid process.
Long head originates from the supraglenoid tubercle.

FACTS TO REMEMBER
- Medial root of median nerve crosses the axillary artery in front to join lateral root to form the median nerve.
- The order of structures from medial to lateral side in the cubital fossa is median nerve, brachial artery, tendon of biceps brachii and radial nerve.
- Triceps brachii is the only active extensor of elbow joint. Gravity extends the joint passively.
- Biceps brachii is a strong supinator of the flexed elbow, besides being its flexor.

CLINICOANATOMICAL PROBLEM
In a motorcycle accident, there was injury to the middle of back of arm.
- What nerve is likely to be injured?
- What muscles are affected? Name five of them.
- What is the effect of injury?

Ans: Due to injury to the middle of back of arm, the radial nerve gets injured. The muscles of arm affected partially are lateral and medial heads of triceps brachii. A part of muscle escapes paralysis as it gets supplied in the axilla.

The other muscles affected are the extensors of forearm. These are brachioradialis, extensor carpi radialis longus and brevis, extensor digitorum and extensor pollicis longus.

The effect of injury is ‘wrist drop’.

FURTHER READING
1. Describe musculocutaneous nerve under following headings:
   a. Root value  
   b. Course  
   c. Branches  
   d. Relations  
   e. Clinical anatomy
2. Enumerate all the boundaries and contents of cubital fossa. Give the clinical importance of the fossa.

**Multiple Choice Questions**

1. Which event does not occur at the insertion of coracobrachialis?
   a. Median nerve crosses brachial artery from the lateral to the medial side  
   b. Ulnar nerve pierces medial intermuscular septum  
   c. Lateral cutaneous nerve of forearm pierces the deep fascia  
   d. Radial nerve pierces lateral intermuscular septum
2. Intersosseous recurrent artery is a branch of which artery?
   a. Ulnar  
   b. Common interosseous  
   c. Anterior interosseous  
   d. Posterior interosseous
3. Which nerve is felt behind medial epicondyle of humerus?
   a. Radial  
   b. Median  
   c. Musculocutaneous  
   d. Ulnar
4. Which of the following nerve injury leads to wrist drop?
   a. Ulnar  
   b. Radial  
   c. Median  
   d. Axillary
5. Lateral boundary of cubital fossa is formed by which muscle?
   a. Biceps brachii  
   b. Brachioradialis  
   c. Brachialis  
   d. Extensor carpi radialis longus
6. Fracture of humerus at mid-shaft is likely to cause injury to which of the following nerves?
   a. Median  
   b. Radial  
   c. Ulnar  
   d. Musculocutaneous
7. Correct order of structures from medial side to lateral side in cubital fossa is:
   a. Median nerve, brachial artery, biceps tendon and radial nerve  
   b. Median nerve, biceps tendon, radial nerve, brachial artery  
   c. Median nerve, brachial artery, radial nerve and biceps tendon  
   d. Brachial artery, median nerve, biceps tendon, radial nerve
8. Which are the heads of triceps brachii muscle?
   a. Long, medial and posterior  
   b. Long, lateral and medial  
   c. Long, lateral and posterior  
   d. Lateral, medial and posterior

8. b

**VIVA VOCE**

- How many compartments are there in the upper arm?
- Name the root value of musculocutaneous nerve.
- Name the events occurring at the level of insertion of coracobrachialis.
- What is name of its cutaneous branch?
• Name the muscles supplied by musculocutaneous nerve.
• Which muscle does coracobrachialis correspond to in lower limb?
• Name the branches of brachial artery.
• What is the clinical importance of brachial artery?
• Name the nerves present on the medial side of brachial artery in its course in upper part and in lower part of arm.
• How is median nerve formed? Why is it called median nerve?
• Name the branches of median nerve in the arm.
• Name the branches of radial nerve in the axilla.
• Which movement will be affected in paralysis of the musculocutaneous nerve?

CUBITAL FOSSA
• What muscle forms lateral boundary of cubital fossa?
• What muscle forms its medial boundary?
• Enumerate the structures forming its roof.
• Name the muscles forming floor of the fossa.
• What are the main contents of the fossa?
• Name the branches of median nerve in the fossa.
• Name the branches of brachial artery in the fossa.
• Name the branches of radial nerve in the fossa.
• What is the clinical importance of bicipital aponeurosis?
• What is clinical importance of cubital fossa?
• Name the heads of triceps brachii muscle and show their origins and insertion.
• Name the regions through which radial nerve passes.
• Name the branches of radial nerve in all these regions.
• What is wrist drop?
• What is the course of profunda brachii artery? Name its branches.
• What does word ‘profunda’ mean?
INTRODUCTION

Forearm extends between the elbow and the wrist joints. Radius and ulna form its skeleton. These two bones articulate at both their ends to form superior and inferior radioulnar joints. Their shafts are kept at optimal distance by the interosseous membrane. Muscles accompanied by nerves and blood vessels are present both on the front and the back of the forearm. Hand is the most distal part of the upper limb, meant for carrying out diverse activities. Numerous muscles, tendons, bursae, blood vessels and nerves are artistically placed and protected in this region.

SURFACE LANDMARKS OF FRONT OF FOREARM

1. The epicondyles of the humerus have been examined (chapter 8). Note that medial epicondyle is more prominent than the lateral (Fig. 9.1). The posterior surface of the medial epicondyle is crossed by the ulnar nerve which can be rolled under the palpating finger. Pressure on the nerve produces tingling sensations on the medial side of the hand (see Fig. 8.13a).

2. The tendon of the biceps brachii can be felt in front of the elbow. It can be made prominent by flexing the elbow joint against resistance. Pulsations of the brachial artery can be felt just medial to the tendon (see Fig. 8.17).

3. The head of the radius can be palpated in a depression on the posterolateral aspect of the extended elbow, distal to the lateral epicondyle. Its rotation can be felt during pronation and supination of the forearm.

4. The styloid process of the radius projects 1 cm lower than the styloid process of the ulna (Fig. 9.51). It can be felt in the upper part of the anatomical snuffbox. Its tip is concealed by the tendons of the abductor pollicis longus and the extensor pollicis brevis, which must be relaxed during palpation.

5. The head of the ulna forms a surface elevation on the medial part of the posterior surface of the wrist when the hand is pronated.

6. The styloid process of the ulna projects downwards from the posteromedial aspect of the lower end of the ulna. Its tip can be felt on the posteromedial aspect of the wrist, where it lies about 1 cm above the tip of the styloid process of the radius (Fig. 9.1).

7. The pisiform bone can be felt at the base of the hypothenar eminence (medially) where the tendon of the flexor carpi ulnaris terminates. It becomes visible and easily palpable at the medial end of the distal transverse crease (junction of forearm and hand) when the wrist is fully extended.

8. The hook of the hamate lies one finger breadth below the pisiform bone, in line with the ulnar border of
the ring finger. It can be felt only on deep palpation through the hypothenar muscles.

9 The tubercle of the scaphoid lies beneath the lateral part of the distal transverse crease in an extended wrist. It can be felt at the base of the thenar eminence in a depression just lateral to the tendon of the flexor carpi radialis (Fig. 9.2).

10 The tubercle (crest) of the trapezium may be felt on deep palpation inferolateral to the tubercle of the scaphoid.

11 The brachioradialis becomes prominent along the lateral border of the forearm when the elbow is flexed against resistance in the midprone position of the hand.

12 The tendons of the flexor carpi radialis, palmaris longus, and flexor carpi ulnaris can be identified on the front of the wrist when the hand is flexed against resistance. The tendons lie in the order stated, from lateral to medial side (Figs 9.3a–c).

13 The pulsation of the radial artery can be felt in front of the lower end of the radius just lateral to the tendon of the flexor carpi radialis.

14 The pulsations of the ulnar artery can be felt by careful palpation just lateral to the tendon of the flexor carpi ulnaris. Here the ulnar nerve lies medial to the artery.

15 The transverse creases in front of the wrist are important landmarks. The proximal transverse crease lies at the level of the wrist joint, and distal crease corresponds to the proximal border of the flexor retinaculum.

16 The median nerve is very superficial in position at and above the wrist. It lies along the lateral edge of the tendon of the palmaris longus at the middle of the wrist.

The muscles of the front of the forearm may be divided into superficial and deep groups.

Components

The front of the forearm presents the following components for study.

1. Eight muscles, five superficial and three deep.
2. Two arteries, radial and ulnar.
3. Three nerves, median, ulnar and radial.

These structures can be better understood by reviewing the long bones of the upper limb and having an articulated hand by the side.
Fig. 9.3b: Dissection of cubital fossa, front of forearm and palm

Figs 9.3c and d: Superficial muscles of front of forearm
**SUPERFICIAL MUSCLES**

There are five muscles in the superficial group. These are the pronator teres, the flexor carpi radialis, the palmaris longus, the flexor carpi ulnaris and the flexor digitorum superficialis (Tables 9.1 and 9.2).

**Common Flexor Origin**

All the superficial flexors of the forearm have a common origin from the front of the medial epicondyle of the humerus. This is called the common flexor origin.

**Additional Features of Superficial Muscles**

1. **Pronator teres**: Pronator teres comprises a big humeral and a smaller ulnar head. Between the two heads, median nerve leaves the cubital fossa. Deep to the two heads exits ulnar artery from cubital fossa into the front of forearm. It forms medial boundary of the cubital fossa. It is the pronator of forearm (Figs 9.5a and 9.11).

2. **Flexor carpi radialis**: It passes through a separate deep compartment of the flexor retinaculum. Flexor carpi radialis gets inserted into anterior aspects of bases of second and third metacarpal bones.

It is easily seen and is a guide to radial pulse which lies lateral to the tendon (Fig. 9.5b).

3. **Palmaris longus**: Palmaris longus (vestigeal muscle) continues as palmar aponeurosis into the palm to protect the nerves and vessels there. Its tendon lies superficial to flexor retinaculum.

4. **Flexor carpi ulnaris**: It is inserted into pisiform bone. Pisiform is a sesamoid bone in this tendon.

5. **Flexor digitorum superficialis**: Flexor digitorum superficialis comprises the humeroulnar and radial heads. The two heads of the muscle are joined by a fibrous arch. Median nerve and ulnar artery pass downwards deep to the fibrous arch (Fig. 9.4).

**DEEP MUSCLES**

Deep muscles of the front of the forearm are the flexor digitorum profundus, the flexor pollicis longus and the pronator quadratus and are described in Tables 9.3 and 9.4. Following are some other points of importance about these muscles.

**Additional Points about the Flexor Digitorum Profundus**

1. It is the most powerful, and most bulky muscle of the forearm. It forms the muscular elevation seen and

The main gripping power of the hand is provided by the flexor digitorum profundus.

The muscle is supplied by two different nerves. So it is a hybrid muscle.

**Additional Points about the Flexor Pollicis Longus**

1. The anterior interosseous nerve and vessels descend on the anterior surface of the interosseous membrane between the flexor digitorum profundus and the flexor pollicis longus (Fig. 9.5).

2. The tendon passes deep to the flexor retinaculum between the opponens pollicis and the oblique head of the adductor pollicis, to enter the fibrous flexor sheath of the thumb. It lies in radial bursa (Fig. 9.7).

**Competency achievement:** The student should be able to:

AN 12.9 Identify and describe fibrous flexor sheaths, ulnar bursa, radial bursa and digital synovial sheaths.

**Synovial Sheaths of Flexor Tendons**

1. **Common flexor synovial sheath (ulnar bursa):** The long flexor tendons of the fingers (flexor digitorum superficialis and profundus) are enclosed in a common synovial sheath while passing deep to the flexor retinaculum (carpal tunnel). The sheath has a parietal layer lining the walls of the carpal tunnel, and a visceral layer closely applied to the tendons (Fig. 9.7). From the arrangement of the sheath, it appears that the synovial sac has been invaginated by the tendons from its lateral side. The synovial sheath extends upwards for 5.0 or 7.5 cm into the forearm and downwards into the palm up to the middle of the shafts of the metacarpal bones. It is important to note that the lower medial end is continuous with the digital synovial sheath of the little finger.

**Fig. 9.4:** Muscles, nerves and arteries seen in the forearm felt on the posterior surface of the forearm medial to the subcutaneous posterior border of the ulna (Fig. 9.6).

**Fig. 9.5b:** Transverse section passing just above wrist showing arrangement of the structures in flexor (anterior) compartment

2 *Synovial sheath of the tendon of flexor pollicis longus (radial bursa):* This sheath is separate. Superiorly, it is coextensive with the common sheath and inferiorly it extends up to the distal phalanx of the thumb (Fig. 9.7).

3 *Digital synovial sheaths:* The sheaths enclose the flexor tendons in the fingers and line the fibrous flexor sheaths. The digital sheath of the little finger is continuous with the ulnar bursa, and that of the thumb with the radial bursa. However, the digital sheaths of the index, middle and ring fingers are separate and independent (Fig. 9.7).

**Vincula Longa and Brevia**

The vincula longa and brevia are synovial folds, which connect the tendons to the phalanges. They transmit vessels to the tendons (Fig. 9.8). These are the remnants of mesotendon.

**DISSECTION**

The skin of the forearm has already been reflected on each side. Cut through the superficial and deep fasciae to expose the superficial muscles of the forearm.
Superficial Muscles
Identify these five superficial muscles. These are from lateral to medial side, pronator teres getting inserted into middle of radius, flexor carpi radialis reaching till the wrist, palmaris longus continuing with palmar aponeurosis, flexor digitorum superficialis passing through the palm and most medially the flexor carpi ulnaris getting inserted into the pisiform bone (Figs 9.3a and b) (refer to BDC App).

Deep Muscles
Cut through the origin of superficial muscles of forearm at the level of medial epicondyle of humerus and reflect them distally. This will expose the three deep muscles, e.g. flexor pollicis longus, flexor digitorum profundus and pronator quadratus (refer to BDC App).

Competency achievement: The student should be able to:

AN 12.2 Identify and describe origin, course, relations, branches (or tributaries), termination of important nerves and vessels of forearm.

ARTERIES OF FRONT OF FOREARM

Features
The most conspicuous arteries of the forearm are the radial and ulnar arteries. However, they mainly supply the hand through the deep and superficial palmar arches. The arterial supply of the forearm is chiefly derived from the common interosseous branch of the ulnar artery, which divides into anterior and posterior interosseous arteries. The posterior interosseous artery is reinforced in the upper part and replaced in the lower part by the anterior interosseous artery.

RADIAL ARTERY

Beginning, Course and Termination
Radial artery (Fig. 9.9) is the smaller terminal branch of the brachial artery in the cubital fossa. It runs downwards to the wrist with a lateral convexity. It leaves the forearm by turning posteriorly and entering the anatomical snuffbox. As compared to the ulnar artery, it is quite superficial throughout its whole course. Its distribution in the hand is described later.
Relations
1 Anteriorly: It is overlapped by the brachioradialis in its upper part, but in the lower half, it is covered only by skin, superficial and deep fasciae.
2 Posteriorly: It is related to the muscles attached to anterior surface of radius, i.e. biceps brachii, flexor pollicis longus, flexor digitorum superficialis and pronator quadratus.
3 Medially: It is related to the pronator teres in the upper one-third and the tendon of the flexor carpi radialis in the lower two-thirds of its course (Figs 9.9 and 9.10).
4 Laterally: Brachioradialis in the whole extent and the radial nerve in the middle one-third.
5 The artery is accompanied by venae comitantes.

Branches in the Forearm
1 The radial recurrent artery arises just below the elbow, runs upwards deep to the brachioradialis, and ends by anastomosing with the radial collateral artery (anterior branch of profunda brachii artery) in front of the lateral epicondylo of the humerus (Fig. 8.10).
2 Muscular branches are given to the lateral muscles of the forearm.

ULNAR ARTERY
Beginning, Course and Termination
Ulnar artery is the larger terminal branch of the brachial artery, and begins in the cubital fossa (Fig. 9.10). The artery runs obliquely downwards and medially in the upper one-third of the forearm; but in the lower two-thirds of the forearm its course is vertical (Fig. 9.4).
enters the palm by passing superficial to the flexor retinaculum. Its distribution in the hand is described later.

**Relations**

1. **Anteriorly**: In its upper half, the artery is deep and is covered by muscles arising from common flexor origin and median nerve. The lower half of the artery is superficial and is covered only by skin and fascia (Fig. 9.4).
2. **Posteriorly**: It lies on brachialis and on the flexor digitorum profundus.
3. **Medially**: It is related to the ulnar nerve, and to the flexor carpi ulnaris (Fig. 9.11).
4. **Laterally**: It is related to the flexor digitorum superficialis (Fig. 9.4) and median nerve.
5. The artery is accompanied by venae comitantes.

**Branches**

1. The *anterior* and *posterior ulnar recurrent arteries* anastomose around the elbow. The smaller anterior ulnar recurrent artery runs up and ends by anastomosing with the inferior ulnar collateral artery in front of the medial epicondyle. The larger posterior ulnar recurrent artery arises lower than the anterior and ends by anastomosing with the superior ulnar collateral artery behind the lateral epicondyle (see Fig. 8.10).
2. The *common interosseous artery* (about 1 cm long) arises just below the radial tuberosity. It passes backwards to reach the upper border of the interosseous membrane, and end by dividing into the anterior and posterior interosseous arteries.

**DISSECTION**

Having dissected the superficial and deep group of muscles of the forearm, identify the terminal branches of the brachial artery, e.g. ulnar and radial arteries and their branches (refer to BDC App).

Radial artery follows the direction of the brachial artery (Fig. 9.9) (refer to BDC App).

Ulnar artery passes obliquely deep to heads of pronator teres and then runs vertically till the wrist. Carefully look for common interosseous branch of ulnar artery and its anterior and posterior branches.

**NERVES OF FRONT OF FOREARM**

Nerves of the front of the forearm are the median, ulnar and radial nerves. The radial and ulnar nerves run along the margins of the forearm, and are never crossed by the corresponding vessels which gradually approach them. The ulnar artery, while approaching the ulnar nerve, gets crossed by the median nerve (Fig. 9.10).
MEDIAN NERVE
Median nerve is the main nerve of the front of the forearm. It also supplies the muscles of thenar eminence (Fig. 9.10).

The median nerve controls coarse movements of the hand, as it supplies most of the long muscles of the front of the forearm. It is, therefore, called the ‘labourer’s nerve’.

Course
Median nerve lies medial to brachial artery and enters the cubital fossa. It is the most medial content of cubital fossa (Fig. 9.11). Then it enters the forearm to lie between flexor digitorum superficialis and flexor digitorum profundus. It lies adherent to the back of superficialis muscle (Fig. 9.5). Then it reaches down the region of wrist where it lies deep and lateral to palmaris longus tendon (Fig. 9.10). Lastly, it passes deep to flexor retinaculum through carpal tunnel to enter the palm (Fig. 9.12).

Relations
1. In the cubital fossa, median nerve lies medial to the brachial artery, behind the bicpital aponeurosis, and in front of the brachialis (see Fig. 8.17).
2. The median nerve enters the forearm by passing between the two heads of the pronator teres. Here it crosses the ulnar artery from which it is separated by the deep head of the pronator teres (Fig. 9.11).
3. Along with the ulnar artery, the median nerve passes beneath the fibrous arch of the flexor digitorum superficialis, and runs deep to this muscle on the surface of the flexor digitorum profundus. It is accompanied by the median artery, a branch of the anterior interosseous artery. About 5 cm above the flexor retinaculum (wrist), it becomes superficial and lies between the tendons of the flexor carpi radialis (laterally) and the flexor digitorum superficialis (medially). It is overlapped by the tendon of the palmaris longus.
4. The median nerve enters the palm by passing deep to the flexor retinaculum through the carpal tunnel.

Branches
1. Muscular branches are given off in the cubital fossa to flexor carpi radialis, palmaris longus and flexor digitorum superficialis (Fig. 9.12).
2. The anterior interosseous branch is given off in the upper part of the forearm. It supplies the flexor pollicis longus, the lateral half of the flexor digitorum profundus (giving rise to tendons for the index and middle fingers) and the pronator quadratus. The nerve also supplies the distal radioulnar and wrist joints (Fig. 9.12).
3. The palmar cutaneous branch arises a short distance above the flexor retinaculum, lies superficial to it and supplies the skin over the thenar eminence and the central part of the palm (see Fig. 7.1a).
4. Articular branches are given to the elbow joint and to the proximal radioulnar joint.
5. Vascular branches supply the radial and ulnar arteries.
6. A communicating branch is given to the ulnar nerve.

ULNAR NERVE
The ulnar nerve is also known as the ‘musician’s nerve’ because it controls fine movements of the fingers. Its course in the palm will be considered in the later part of this chapter.

Course
Ulnar nerve is palpable as it lies behind medial epicondyle of humerus and is not a content of cubital fossa (Fig. 9.13). It enters the forearm by passing
between two heads of flexor carpi ulnaris, i.e. cubital tunnel, to lie along the lateral border of flexor carpi ulnaris in the forearm. In the last phase, it courses superficial to the flexor retinaculum, covered by its superficial slip or volar carpal ligament to enter the region of palm.

**Relations**

1. At the elbow, the ulnar nerve lies behind the medial epicondyle of the humerus (Fig. 9.10). It enters the forearm by passing between the two heads of the flexor carpi ulnaris.
2. In the forearm, the ulnar nerve runs on the medial part of the flexor digitorum profundus muscle.
3. At the wrist, the ulnar neurovascular bundle lies between the flexor carpi ulnaris and the flexor digitorum profundus. The bundle enters the palm by passing superficial to the flexor retinaculum, lateral to the pisiform bone (Fig. 9.13).

**Branches**

1. Muscular, to the flexor carpi ulnaris and the medial half of the flexor digitorum profundus.
2. Palmar cutaneous branch arises in the middle of the forearm and supplies the skin over the hypothenar eminence (see Fig. 7.1a).
3. Dorsal cutaneous branch arises 7.5 cm above the wrist, winds backwards and supplies the proximal parts of the medial 2½ digits and the adjoining area of the dorsum of the hand (see Fig. 7.1b).
4. Articular branches are given off to the elbow joint.
5. Its branches in the palm are shown in Figs 9.13 and 9.34.

**RADIAL NERVE**

**Course**

The radial nerve divides into its two terminal branches in the cubital fossa just below the level of the lateral epicondyle of the humerus (Fig. 9.10).

**Branches**

The deep terminal branch (posterior interosseous) soon enters the back of the forearm by passing through the supinator muscle. It will be studied further in back of forearm as posterior interosseous nerve.

The superficial terminal branch (the main continuation of the nerve) runs down in front of the forearm.

The superficial terminal branch of the radial nerve is closely related to the radial artery only in the middle one-third of the forearm (Fig. 9.10). It is purely cutaneous. In the upper one-third, it is widely separated from the artery, and in the lower one-third it passes backwards under the tendon of the brachioradialis to reach the anatomical snuffbox from where it is distributed to the lateral half of the dorsum of the hand, and to the proximal parts of the dorsal surfaces of the thumb, the index finger, and lateral half of the middle finger (see Fig. 7.1b).

Injury to this branch results in small area of sensory loss over the root of the thumb.

**DISSECTION**

Median nerve is the chief nerve of the forearm. It enters the forearm by passing between two heads of pronator teres muscle. Its anterior interosseous branch is given off as it is leaving the cubital fossa. Identify median nerve stuck to the fascia on the deep surface of flexor digitorum superficialis muscle. Thus, the nerve lies deep to the flexor digitorum superficialis (Fig. 9.4).

Dissect the anterior interosseous nerve as it lies on the interosseous membrane between flexor pollicis longus and flexor digitorum profundus muscles (Fig. 9.5a).

Identify the ulnar nerve situated behind the medial epicondyle. Trace it vertically down till the flexor retinaculum (Figs 9.10 and 9.11) (refer to BDC App).
Trace the radial nerve and its two branches in the lateral part of the cubital fossa. Its deep branch is muscular and superficial branch is cutaneous (Fig. 9.11).

**PALMAR ASPECT OF WRIST AND HAND**

**Features**
The human hand is designed:

i. For grasping,
ii. For precise movements, and
iii. For serving as a tactile organ.

There is a big area in the motor cortex of brain for muscles of hand.

The skin of the palm is:

i. Thick for protection of underlying tissues.
ii. Immobile because of its firm attachment to the underlying palmar aponeurosis.
iii. Creased. All of these characters increase the efficiency of the grip.

The skin is supplied by spinal nerves C6–C8 (see Fig. 7.1a) through the median and ulnar nerves.

The superficial fascia of the palm is made up of dense fibrous bands which bind the skin to the deep fascia (palmar aponeurosis) and divide the subcutaneous fat into small tight compartments which serve as water-cushions during firm gripping. The fascia contains a subcutaneous muscle, the palmaris brevis, which helps in improving the grip by steadying the skin on the ulnar side of the hand. The superficial metacarpal ligament which stretches across the roots of the fingers over the digital vessels and nerves, is a part of this fascia.

The deep fascia is specialised to form:

i. The flexor retinaculum at the wrist.
ii. The palmar aponeurosis in the palm.
iii. The fibrous flexor sheaths in the fingers.

All three form a continuous structure which holds the tendons in position and thus increase the efficiency of the grip.

**DISSECTION**

1. A horizontal incision at the distal crease of front of the wrist has already been made.
2. Make a vertical incision from the centre of the above incision through the palm to the centre of the middle finger (Fig. 9.14).
3. Make one horizontal incision along the distal palmar crease.
4. Make an oblique incision starting 3 cm distal to incision no. 2 and extend it till the tip of the distal phalanx of the thumb.
Thus the skin of the palm gets divided into three areas. Reflect the skin of lateral and medial flaps on their respective sides. The skin of the intermediate flap is reflected distally towards the distal palmar crease. Further the skin of middle finger is to be reflected on either side.

**Superficial fascia and deep fascia**

Remove the superficial fascia to clean the underlying deep fascia.

Deep fascia is modified to form the flexor retinaculum at wrist, palmar aponeurosis in the palm, and fibrous flexor sheaths in the digits. Identify the structures on its superficial surface. Divide the flexor retinaculum between the thenar and hypothenar eminences, carefully preserving the underlying median nerve and long flexor tendons (refer to BDC App).

Identify long flexor tendons enveloped in their synovial sheaths including the digital synovial sheaths.

**Competency achievement:** The student should be able to:

AN 12.3 Identify and describe flexor retinaculum with its attachments.

**Flexor Retinaculum**

Flexor retinaculum (Latin to hold back) is a strong fibrous band which bridges the anterior concavity of the carpus and converts it into a tunnel, the carpal tunnel (Fig. 9.15).

**Attachments**

Medially, to:

1. The pisiform bone, and
2. The hook of the hamate.

Laterally, to:

1. The tubercle of the scaphoid, and
2. The crest of the trapezium.
On either side, the retinaculum has a slip:

1. The lateral deep slip is attached to the medial lip of the groove on the trapezium which is thus converted into a tunnel for the tendon of the flexor carpi radialis.
2. The medial superficial slip (volar carpal ligament) is also attached to the pisiform bone. The ulnar vessels and nerves pass deep to this slip (Fig. 9.15).

**Relations**

The structures passing superficial to the flexor retinaculum are:

i. The palmar cutaneous branch of the median nerve (Fig. 9.16).
ii. The tendon of the palmaris longus.
iii. The palmar cutaneous branch of the ulnar nerve.
iv. The ulnar vessels.
v. The ulnar nerve.

The thenar and hypothenar muscles arise from the retinaculum (Fig. 9.15).

The structures passing deep to the flexor retinaculum are:

i. The median nerve (Fig. 9.15).
ii. Four tendons of the flexor digitorum superficialis.
iii. Four tendons of the flexor digitorum profundus.
iv. The tendon of the flexor pollicis longus.
v. The ulnar bursa.
vi. The radial bursa.
vii. The tendon of the flexor carpi radialis lies between the retinaculum and its deep slip, in the groove on the trapezium (Fig. 9.15).

**Palmar Aponeurosis**

This term is often used for the entire deep fascia of the palm. However, it is better to restrict this term to the central part of the deep fascia of the palm which covers the superficial palmar arch, the long flexor tendons, the terminal part of the median nerve, and the superficial branch of the ulnar nerve (Fig. 9.16).

**Features**

Palmar aponeurosis is triangular in shape. The apex which is proximal, blends with the flexor retinaculum
and is continuous with the tendon of the palmaris longus. The base is directed distally. It divides into superficial and deep strata, superficial is attached to dermis. Deep strata divides into four slips opposite the heads of the metacarpals of the medial four digits. Each slip divides into two parts which are continuous with the fibrous flexor sheaths. Extensions pass to the deep transverse metacarpal ligament, the capsule of the metacarpophalangeal joints and the sides of the base of the proximal phalanx. The digital vessels and nerves, and the tendons of the lumbricals emerge through the intervals between the slips. From the lateral and medial margins of the palmar aponeurosis, the lateral and medial palmar septa pass backwards and divide the palm into compartments.

Functions
Palmar aponeurosis fixes the skin of the palm and thus improves the grip. It also protects the underlying tendons, vessels and nerves.

Fibrous Flexor Sheaths of the Fingers
The fibrous flexor sheaths are made up of the deep fascia of the fingers. The fascia is thick and arched. It is attached to the sides of the phalanges and across the base of the distal phalanx. Proximally, it is continuous with a slip of the palmar aponeurosis.

In this way, a blind osseofascial tunnel is formed which contains the long flexor tendons enclosed in the digital synovial sheath (Figs 9.17a–c). The fibrous sheath is thick opposite the phalanges and thin opposite the joints to permit flexion.

The sheath holds the tendons in position during flexion of the digits.

CLINICAL ANATOMY

Dupuytren’s contracture: This condition is due to inflammation involving the ulnar side of the palmar aponeurosis. There is thickening and contraction of the aponeurosis. As a result, the proximal phalanx and later the middle phalanx become flexed and cannot be straightened. The terminal phalanx remains unaffected. The ring finger is most commonly involved (Fig. 9.18).
INTRINSIC MUSCLES OF HAND

Features
The intrinsic muscles of the hand serve the function of adjusting the hand during gripping and also for carrying out fine skilled movements. Their attachments, nerve supply and actions are given in Tables 9.5 and 9.6.

There are 20 muscles in the hand. These are:

1. Three muscles of thenar eminence
   1. Abductor pollicis brevis (Fig. 9.19)
   2. Flexor pollicis brevis
   3. Opponens pollicis
2. One adductor of thumb: Adductor pollicis.
3. Four hypothenar muscles
   1. Palmaris brevis
   2. Abductor digiti minimi
   3. Flexor digiti minimi (Fig. 9.20)
   4. Opponens digiti minimi (Fig. 9.22)
   Muscles (ii) to (iv) are muscles of hypothenar eminence.
4. Four lumbricals (Fig. 9.21)
5. Four palmar interossei (Figs 9.23, 9.24b and c)
6. Four dorsal interossei (Figs 9.23, 9.24a and c)
   These muscles are described in Tables 9.5 and 9.6.

Actions of Thenar Muscles
In studying the actions of the thenar muscles, it must be remembered that the movements of the thumb take place in planes at right angles to those of the other digits because the thumb (first metacarpal) is rotated medially through 90°. Flexion and extension of the thumb take place in the plane of the palm; while abduction and adduction at right angles to the plane of palm. Movement of the thumb across the palm to touch the other digits is known as ‘opposition’. This movement is a combination of flexion and medial rotation.

Actions of Dorsal Interossei
All dorsal interossei cause abduction of the digits away from the line of the middle finger. This movement occurs in the plane of palm (Fig. 9.25) in contrast to the movement of thumb where abduction occurs at right angles to the plane of palm (Fig. 9.26). Note that movement of the middle finger to either medial or lateral side constitutes abduction. Also note that the first and fifth digits do not require dorsal interossei as they have their own abductors.

Testing of Some Intrinsic Muscles
a. Pen/pencil test for abductor pollicis brevis: Lay the hand flat on a table with the palm directed upwards. The patient is unable to touch with his thumb a pen/pencil held in front of the palm (Fig. 9.27).
b. Test for opponens pollicis: Request the patient to touch the proximal phalanx of 2nd to 5th digits with the tip of thumb.

MC: Metacarpal

c. The dorsal interossei are tested by asking the subject to spread out the fingers against resistance. As index finger is abducted one feels 1st dorsal interosseous (Fig. 9.28).
d. The palmar interossei and adductor pollicis are tested by placing a piece of paper between the fingers (Fig. 9.29), between thumb and index finger and seeing how firmly it can be held (Fig. 9.30).
e. Froment’s sign, or the book test which tests the adductor pollicis muscle. When the patient is asked to grasp a book firmly between the thumbs and other fingers of both the hands, the terminal phalanx of the thumb on the paralysed side becomes flexed at the interphalangeal joint (by the flexor pollicis longus which is supplied by the median nerve) (Fig. 9.31).
f. The lumbricals and interossei are tested by asking the subject to flex the fingers at the metacarpophalangeal joints against resistance.
Competency achievement: The student should be able to:

**AN 12.7** Identify and describe course and branches of important blood vessels and nerves in hand.

### ARTERSIES OF HAND

#### Features
Arteries of the hand are the terminal parts of the ulnar and radial arteries. Branches of these arteries unite and form anastomotic channels called the superficial and deep palmar arches.

#### Ulnar Artery
The course of this artery in the forearm has been described earlier. It enters the palm by passing superficial to the flexor retinaculum but deep to volar carpal ligament (Figs. 9.15). It ends by dividing into the superficial palmar branch, which is the main continuation of the artery, and the deep palmar branch. These branches take part in the formation of the superficial palmar arch and deep palmar arch, respectively.

#### Superficial Palmar Arch
The arch represents an important anastomosis between the ulnar and radial arteries.

- The convexity of the arch is directed towards the fingers, and its most distal point is situated at the level of the distal border of the fully extended thumb.

#### Formation
The superficial palmar arch is formed as the direct continuation of the ulnar artery beyond the flexor retinaculum, i.e. by the superficial branch of the ulnar artery. On the lateral side, the arch is completed by the superficial branch of the radial artery. Identify its common and proper digital branches.

#### Relations
- The arch lies deep to the palmar aponeurosis, identify the superficial palmar arch formed mainly by superficial branch of ulnar and superficial palmar branch of radial artery. Identify its common and proper digital branches.

### DISSECTION

Clean the thenar and hypothenar muscles. Carefully preserve the median nerve and superficial and deep branches of ulnar nerve which supply these muscles.

- **Abductor pollicis brevis** is the lateral muscle; **flexor pollicis brevis** is the medial one. Both these form the superficial lamina. The deeper lamina is constituted by **opponens pollicis** (Figs. 9.19 to 9.22).

- **Incise flexor pollicis brevis in its centre and reflect its two parts.** This will reveal the tendon of **flexor digiti minimi** just lateral to it. Identify these three muscles and trace their nerve supply from deep branch of ulnar nerve (**refer to BDC App**).

- **Between the two eminences of the palm, deep to palmar aponeurosis, identify the superficial palmar arch formed mainly by superficial branch of ulnar and superficial palmar branch of radial artery.** Identify its common and proper digital branches.

- **Clean, dissect and preserve the branches of the median nerve and superficial division of ulnar nerve in the palm lying between the superficial palmar arch and long flexor tendons (**refer to BDC App**).**

- **Lying on a deeper plane are the tendons of flexor digitorum superficialis muscle.** Dissect the peculiar mode of its insertion in relation to that of tendon of flexor digitorum profundus (Fig. 9.21).

- **Cut through the tendons of flexor digitorum superficialis 5 cm above the wrist. Divide both ends of superficial palmar arch.** Reflect them distally towards the metacarpophalangeal joints.

- **Identify four tendons of flexor digitorum profundus diverging in the palm with four delicate muscles, the lumbricals, arising from them. Dissect the nerve supply to these lumbricals.** The first and second are supplied from median and third and fourth from the deep branch of ulnar nerve (Fig. 9.21).

- **Divide the flexor digitorum profundus 5 cm above the wrist and reflect it towards the metacarpophalangeal joints.** Trace one of its tendons to its insertion into the base of distal phalanx of one finger (**refer to BDC App**).
UPPER LIMB

Relations
1. It leaves the forearm by winding backwards round the wrist.
2. It passes through the anatomical snuffbox where it lies deep to the tendons of the abductor pollicis longus, the extensor pollicis brevis and the extensor pollicis longus. It is also crossed by the digital branches of the radial nerve.
3. It reaches the proximal end of the first interosseous space and passes between the two heads of the first dorsal interosseous muscle to reach the palm.
4. In the palm, the radial artery runs medially. At first it lies deep to the oblique head of the adductor pollicis, and then passes between the two heads of this muscle to form the deep palmar arch. Therefore, it is known as the deep palmar arch (Fig. 9.33).

Branches
Dorsum of hand: On the dorsum of the hand, the radial artery gives off:
1. A branch to the lateral side of the dorsum of the thumb.
2. The first dorsal metacarpal artery. This artery arises just before the radial artery passes into the interval between the two heads of the first dorsal interosseous muscle.

CLINICAL ANATOMY
The radial artery is used for feeling the (arterial) pulse at the wrist. The pulsations can be felt well in this situation because of the presence of the flat radius with pronator quadratus muscle behind the artery (Fig. 9.10).

RADIAL ARTERY
In this part of its course, the radial artery runs obliquely downwards, and backwards deep to the tendons of the abductor pollicis longus, the extensor pollicis brevis, and the extensor pollicis longus, and superficial to the lateral ligament of the wrist joint (Fig. 9.52a). Thus it passes through the anatomical snuffbox to reach the proximal end of the first interosseous space. Further, it passes between the two heads of the first dorsal interosseous muscle and between the two heads of adductor pollicis to form the deep palmar arch in the palm (Fig. 9.33).

Course
Radial artery runs obliquely from the site of ‘radial pulse’ to reach the anatomical snuffbox. From there, it passes forwards to reach first interosseous space and then into the palm.

Fig. 9.32: The superficial and deep palmar arches
muscle. It at once divides into two branches for the adjacent sides of the thumb and the index finger.

**Palm:** In the palm (deep to the oblique head of the adductor pollicis), the radial artery gives off:

1. The *princeps pollicis artery* which divides at the base of the proximal phalanx into two branches for the palmar surface of the thumb (Fig. 9.33).
2. The *radialis indicis artery* descends between the first dorsal interosseous muscle and the transverse head of the adductor pollicis to supply the lateral side of the index finger.

**Deep Palmar Arch**

Deep palmar arch provides a second channel connecting the radial and ulnar arteries in the palm (the first one being the superficial palmar arch already considered). It is situated deep to the long flexor tendons.

**Formation**

The deep palmar arch is formed mainly by the terminal part of the radial artery, and is completed medially at the base of the fifth metacarpal bone by the deep palmar branch of the ulnar artery (Fig. 9.32).

**Relations**

The arch lies on the proximal parts of the shafts of the metacarpals, and on the interossei; under the cover of the oblique head of the adductor pollicis, the flexor tendons of the fingers, and the lumbricals.

The deep branch of the ulnar nerve lies within the concavity of the arch.

**Branches**

1. From its convexity, i.e. from its distal side, the arch gives off three *palmar metacarpal arteries*, which run distally in the 2nd, 3rd and 4th spaces, supply the medial four metacarpals, and terminate at the finger clefts by joining the common digital branches of the superficial palmar arch (Fig. 9.32).
2. Dorsally, the arch gives off three (proximal) *perforating digital arteries* which pass through the medial three interosseous spaces to anastomose with the dorsal metacarpal arteries.

**DISSECTION**

Deep to the lateral two tendons of flexor digitorum profundus muscle, note an obliquely placed muscle extending from two origins, i.e. from the shaft of the third metacarpal bone and the bases of 2nd and 3rd metacarpal bones and adjacent carpal bones to the base of proximal phalanx of the thumb. This is *adductor pollicis brevis*.
pollicis (Fig. 9.22). Reflect the adductor pollicis muscle from its origin towards its insertion.

Identify the deeply placed interossei muscles. Identify the radial artery entering the palm between two heads of first dorsal interosseous muscle and then between two heads of adductor pollicis muscle turning medially to join the deep branch of ulnar artery to complete the deep palmar arch (Fig. 9.32). Identify the deep branch of ulnar nerve lying in its concavity. Carefully preserve it, including its multiple branches. Deep branch of ulnar nerve ends by supplying the adductor pollicis muscle. It may supply deep head of flexor pollicis brevis also.

Lastly, define four small palmar interossei and four relatively bigger dorsal interossei muscles (Figs 9.23 and 9.24a–c) (refer to BDC App).

NERVES OF HAND

ULNAR NERVE

Ulnar nerve is the main nerve of the hand (like the lateral plantar nerve in the foot).

Course

Ulnar nerve lies superficial to flexor retinaculum, covered only by the superficial slip of the retinaculum (volar carpal ligament—Fig. 9.15). It terminates by dividing into a superficial and a deep branch.

Superficial branch is cutaneous. The deep branch passes through the muscles of the hypothenar eminence to lie in the concavity of the deep palmar arch to end in the adductor pollicis (Fig. 9.22).

Relations

1. The ulnar nerve enters the palm by passing superficial to the flexor retinaculum where it lies between the pisiform bone and the ulnar vessels. Here the nerve divides into its superficial and deep terminal branches (Figs 9.13).
2. The superficial terminal branch supplies the palmaris brevis and divides into two digital branches for the medial 1½ fingers (Fig. 9.34a).
3. The deep terminal branch accompanies the deep branch of the ulnar artery. It passes backwards between the abductor and flexor digiti minimi, and then between the opponens digiti minimi and the fifth metacarpal bone, lying on the hook of the hamate. Finally, it turns laterally within the concavity of the deep palmar arch. It ends by supplying the adductor pollicis muscle (Fig. 9.22).

Branches

From Superficial Terminal Branch

1. Muscular branch: To palmaris brevis.
2. Cutaneous branches: Two palmar digital nerves supply the medial 1½ fingers with their nail beds (Fig. 9.34a).
   - The medial branch supplies the medial side of the little finger.
   - The lateral branch is a common palmar digital nerve. It divides into two proper palmar digital nerves for the adjoining sides of the ring and little fingers.
   - The common palmar digital nerve communicates with the median nerve.

Figs 9.34a and b: Distribution of the branches of the ulnar nerve
From Deep Terminal Branch

1 Muscular branches:
   a. At its origin, the deep branch supplies three muscles of hypothenar eminence (Fig. 9.34b).
   b. As the nerve crosses the palm, it supplies the medial two lumbricals and eight interossei.
   c. The deep branch terminates by supplying the adductor pollicis, and occasionally the deep head of the flexor pollicis brevis.

2 An articular branch supplies the wrist joint.

CLINICAL ANATOMY

- The ulnar nerve is also known as the ‘musician’s nerve’ because it controls fine movements of the fingers (Fig. 9.34a).
- The ulnar nerve is commonly injured at the elbow, behind the medial epicondyle or distal to elbow as it passes between two heads of flexor carpi ulnaris (cubital tunnel) or at the wrist in front of the flexor retinaculum.
  Ulnar nerve injury at the elbow: Flexor carpi ulnaris and the medial half of the flexor digitorum profundus are paralysed.
- Due to this paralysis, the medial border of the forearm becomes flattened. An attempt to produce flexion at the wrist results in abduction of the hand. The tendon of the flexor carpi ulnaris does not tighten on making a fist. Flexion of the terminal phalanges of the ring and little fingers is lost.
- The ulnar nerve controls fine movements of the fingers through its extensive motor distribution to the short muscles of the hand. There is ulnar claw hand as well.
  Ulnar nerve lesion at the wrist: Produces ‘ulnar claw-hand’.
- Ulnar claw hand is characterised by the following signs.
  a. Hyperextension at the metacarpophalangeal joints and flexion at the interphalangeal joints, involving the ring and little fingers—more than the index and middle fingers (Fig. 9.35). The intermetacarpal spaces are hollowed out due to wasting of the interosseous muscles. Claw hand deformity is more obvious in wrist lesions as the profundus muscle is spared: This causes marked flexion of the terminal phalanges (action of paradox) (see p 197).
  b. Sensory loss is confined to the medial one-third of the palm and the medial 1½ fingers including their nail beds (Figs. 9.36a and b). Medial half of dorsum of hand also shows sensory loss.
  c. Vasomotor changes: The skin areas with sensory loss is warmer due to arteriolar dilatation; it is also drier due to absence of sweating because of loss of sympathetic supply.
  d. Trophic changes: Long-standing cases of paralysis lead to dry and scaly skin. The nails crack easily with atrophy of the pulp of fingers.
  e. The patient is unable to spread out the fingers due to paralysis of the dorsal interossei. The power of adduction of the thumb, and flexion of the ring and little fingers are lost. It should be noted that median nerve lesions are more disabling. In contrast, ulnar nerve lesions leave a relatively efficient hand.

Fig. 9.35: Clawing of ring and little fingers

Figs 9.36a and b: Sensory loss on: (a) Palmar aspect, and (b) dorsal aspect of hand in ulnar nerve injury
MEDIAN NERVE
The median nerve is important because of its role in controlling the movements of the thumb which are crucial in the mechanism of gripping by the hand.

Course
Median nerve lies deep to flexor retinaculum in the carpal tunnel and enters the palm (Fig. 9.20). Soon it terminates by dividing into muscular and cutaneous branches.

Relations
1 The median nerve enters the palm by passing deep to the flexor retinaculum where it lies in the narrow space of the carpal tunnel in front of the ulnar bursa enclosing the flexor tendons.

Immediately, below the retinaculum, the nerve divides into lateral and medial divisions (Fig. 9.20).

2 The lateral division gives off a muscular branch to the thenar muscles, and three digital branches for the lateral 1½ digits including the thumb.

The muscular branch curls upwards around the distal border of the retinaculum and supplies the thenar muscles.

Out of the three digital branches, two supply the thumb and one the lateral side of the index finger.

The digital branch to the index finger also supplies the first lumbrical (Fig. 9.37).

3 The medial division divides into two common digital branches for the second and third interdigital clefts, supplying the adjoining sides of the index, middle and ring fingers.

The lateral common digital branch also supplies the second lumbrical.

Branches
In the hand, the median nerve supplies:

- a. Five muscles, namely the abductor pollicis brevis, the flexor pollicis brevis, the opponens pollicis and the first and second lumbrical muscles.
- b. Palmar skin over the lateral 3½ digits with their nail beds.

Competency achievement: The student should be able to:

AN 12.4 Explain anatomical basis of carpal tunnel syndrome.

AN 12.8 Describe anatomical basis of claw hand.

CLINICAL ANATOMY
- The median nerve controls coarse movements of the hand, as it supplies most of the long muscles of the front of the forearm. It is, therefore, called the _labourer’s nerve_. It is also called ‘eye of the hand’ as it is sensory to most of the hand.
- When the median nerve is injured above the level of the elbow, as might happen in _supracondylar fracture of the humerus_, the following features are seen.
  a. The flexor pollicis longus and lateral half of flexor digitorum profundus are paralysed. The patient is unable to bend the terminal phalanx of the thumb and index finger when the proximal phalanx is held firmly by the clinician (to eliminate the action of the short flexors) (Fig. 9.38). Similarly, the terminal phalanx of the middle finger can be tested.
  b. The forearm is kept in a supine position due to paralysis of the pronators.
c. The hand is adducted due to paralysis of the flexor carpi radialis, and flexion at the wrist is weak.
d. Flexion at the interphalangeal joints of the index and middle fingers is lost so that the index and the middle (to a lesser extent) fingers tend to remain straight while making a fist. This is called pointing index finger, occurs due to paralysis of long flexors of the digit (Fig. 9.39).
e. Ape or monkey-like thumb deformity is present due to paralysis of the thenar muscles (Fig. 9.40).
f. The area of sensory loss corresponds to its distribution (Fig. 9.41) in the hand.
g. Vasomotor and trophic changes: The skin on lateral 3½ digits is warm, dry and scaly. The nails get cracked easily (Fig. 9.42).

- **Carpal tunnel syndrome (CTS):** Involvement of the median nerve in carpal tunnel at wrist has become a very common entity (Fig. 9.15).
a. This syndrome consists of motor, sensory, vasomotor and trophic symptoms in the hand caused by compression of the median nerve in the carpal tunnel. Examination reveals wasting of thenar eminence (ape-like hand), hypoaesthesia to light touch on the palmar aspect of lateral 3½ digits. However, the skin over the thenar eminence is not affected as the branch of median nerve supplying it arises in the forearm.

b. Froment’s sign/book holding test: The patient is unable to hold the book with thumbs and other fingers.

c. Paper holding test: The patient is unable to hold paper between thumb and fingers. Both these tests are positive because of paralysis of thenar muscles.

d. Motor changes: Ape-/monkey-like thumb deformity (Fig. 9.40), loss of opposition of thumb. Index and middle fingers lag behind while making the fist due to paralysis of 1st and 2nd lumbrical muscles (Fig. 9.43).

e. Sensory changes: Loss of sensations on lateral 3½ digits including the nail beds and distal phalanges on dorsum of hand (Fig. 9.41).

f. Vasomotor changes: The skin areas with sensory loss is warmer due to arteriolar dilatation; it is also drier due to absence of sweating due to loss of sympathetic supply.

g. Trophic changes: Long-standing cases of paralysis lead to dry and scaly skin. The nails crack easily with atrophy of the pulp of fingers (Fig. 9.42).

h. It occurs both in males and females between the age of 25 and 70. They complain of intermittent attacks of pain in the distribution of the median nerve on one or both sides. The attacks frequently occur at night. Pain may be referred proximally to the forearm and arm. It is more common because of excessive working on the computer. Phalen’s test (Fig. 9.44) is attempted for CTS.

- Complete claw hand: If both median and ulnar nerves are paralysed, the result is complete claw hand (Fig. 9.45).

RADIAL NERVE

The part of the radial nerve seen in the hand is a continuation of the superficial terminal branch. It reaches the dorsum of the hand (after winding round
the lateral anatomical snuffbox on side of the radius) and divides into 4 dorsal digital branches which supply the skin of the digits as follows (see Fig. 7.1).

1st: Lateral side of thumb
2nd: Medial side of thumb
3rd: Lateral side of index finger
4th: Contiguous sides of index and middle fingers

Note that skin over the dorsum of the distal phalanges is supplied by the median nerve (not radial) (Fig. 9.46). Sensory loss is less because of overlapping of nerves.

**Palmar Spaces**

**Pulp Space of the Fingers**
The tips of the fingers and thumb contain subcutaneous fat arranged in tight compartments formed by fibrous septa which pass from the skin to the periosteum of the terminal phalanx. Infection of this space is known as whitleow. The rising tension in the space gives rise to severe throbbing pain.

Infections in the pulp space (whitleow) can be drained by a lateral incision which opens all compartments and avoids damage to the tactile tissue in front of the finger.

If neglected, a whitleow may lead to necrosis of the distal four-fifths of the terminal phalanx due to occlusion of the vessels by the tension. The proximal one-fifth (epiphysis) escapes because its artery does not traverse the fibrous septa (Fig. 9.47).

**Midpalmar and Thenar Spaces**

Midpalmar and thenar spaces are shown in Table 9.7 and Fig. 9.48.

**Dorsal Spaces**
The dorsal subcutaneous space lies immediately deep to the loose skin of the dorsum of the hand. The dorsal subaponeurotic space lies between the metacarpal bones and the extensor tendons which are united to one another by a thin aponeurosis.

**Forearm Space of Parona**

Forearm space of Parona is a rectangular space situated deep in the lower part of the forearm just above the wrist. It lies in front of the pronator quadratus, and deep to the long flexor tendons. Superiorly, the space extends up to the oblique origin of the flexor digitorum superficialis. Inferiorly, it extends up to the flexor retinaculum, and communicates with the midpalmar space. The proximal part of the flexor synovial sheaths protrudes into the forearm space.

**Competency achievement:** The student should be able to:

**AN 12.10** Explain infection of fascial spaces of palm.

---

![Fig. 9.46: Sensory loss in injury to superficial branch of radial nerve](image)

**FASCIAL SPACES OF HAND**

Having learnt the anatomy of the whole hand, the clinically significant spaces of the hand need to be understood and their boundaries to be identified from the following text.

The arrangement of fasciae and the fascial septa in the hand is such that many spaces are formed. These spaces are of surgical importance because they may become infected and distended with pus. The important spaces are as follows.

A. **Palmar spaces**
   1. Pulp space of the fingers
   2. Midpalmar space
   3. Thenar space

B. **Dorsal spaces**
   1. Dorsal subcutaneous space
   2. Dorsal subaponeurotic space

C. **The forearm space of Parona.**

![Fig. 9.47: The digital pulp space](image)
The forearm space may be infected through infections in the related synovial sheaths, especially of the ulnar bursa. Pus points at the margins of the distal part of the forearm where it may be drained by giving incision along the lateral margin of forearm.

SYNOVIAL SHEATHS
Many of the tendons entering the hand are surrounded by synovial sheaths. The extent of these sheaths is of surgical importance as they can be infected (Fig. 9.7).
**BACK OF FOREARM AND HAND**

This section deals mainly with the extensor retinaculum of the wrist, muscles of the back of the forearm, the deep terminal branch of the radial nerve, and the posterior interosseous artery.

**SURFACE LANDMARKS**

1. The **olecranon process** of the ulna is the most prominent bony point on the back of a flexed elbow (Fig. 9.51). Normally, it forms a straight horizontal line with the two epicondyles of the humerus when the elbow is extended, and an equilateral triangle when the elbow is flexed to a right angle (see Fig. 2.17). The relative position of the three bony points is disturbed when the elbow is dislocated.

2. The **head of the radius** can be palpated in a depression on the posterolateral aspect of an extended elbow just below the lateral epicondyle of the humerus. Its rotation can be felt during pronation and supination of the forearm.

3. The **posterior border of the ulna** is subcutaneous in its entire length. It can be felt in a longitudinal groove on the back of the forearm when the elbow is flexed and the hand is supinated. The border ends distally in the styloid process of the ulna. It separates the flexors from the extensors of the forearm. Being superficial, it allows the entire length of the ulna to be examined for fractures.

4. The **head of the ulna** forms a surface elevation on the posteromedial aspect of the wrist in a pronated forearm.

5. The **styloid processes of the radius and ulna** are important landmarks of the wrist. The styloid process of the radius can be felt in the upper part of the anatomical snuffbox. It projects down 1 cm lower than the styloid process of the ulna. The latter descends from the posteromedial aspect of the ulnar head. The relative position of the two styloid processes is disturbed in fractures at the wrist, and is a clue to the proper realignment of fractured bones.

6. The **dorsal tubercle of the radius** (Lister’s tubercle) can be palpated on the dorsal surface of the lower end of the radius in line with the cleft between the index and middle fingers. It is grooved on its medial side by the tendon of the extensor pollicis longus.

7. The heads of the metacarpals form the knuckles.

---

**DORSUM OF HAND**

1. **Skin**: It is loose on the dorsum of hand. It can be pinched off from the underlying structures.

2. **Superficial fascia**: The fascia contains dorsal venous plexus, cutaneous nerves, and dorsal carpal arch.
a. *Dorsal venous plexus*: The digital veins from adjacent sides of index, middle, ring and little fingers form 3 dorsal metacarpal veins (see Fig. 7.7). These join with each other on dorsum of hand. The lateral end of this arch is joined by one digital vein from index finger and two digital veins from thumb to form cephalic vein. It runs proximally in the anatomical snuffbox, curves, round the lateral border of wrist to come to front of forearm. In a similar manner, the medial end of the arch joins with one digital vein only from medial side of little finger to form basilic vein. It also curves around the medial side of wrist to reach front of forearm. These metacarpal veins may unite in different ways to form a dorsal venous plexus.

b. *Cutaneous nerves*: These are superficial branch of radial nerve and dorsal branch of ulnar nerve. The nail beds and skin of distal phalanges of 3½ lateral nails is supplied by median nerve and 1½ medial nails by ulnar nerve. The superficial branch of radial nerve supplies lateral half of dorsum of hand with two digital branches to thumb and one to lateral side of index and another common digital branch to adjacent sides of index and middle fingers (see Fig. 7.1b). Dorsal branch of ulnar supplies medial half of dorsum of hand with proper digital branches to medial side of little finger; two common digital branches for adjacent sides of little and ring fingers and adjacent sides of ring and middle fingers.

c. *Dorsal carpal arch*: It is formed by dorsal carpal branches of radial and ulnar arteries and lies close to the wrist joint. The arch gives three dorsal metacarpal arteries which supply adjacent sides of index, middle; ring and little fingers. One digital artery goes to medial side of little finger. The arch also gives branches to the dorsum of hand.

3 *Spaces on dorsum of hand*: There are two spaces on the dorsum of hand:

a. *Dorsal subcutaneous space*, lying just subjacent to skin. Skin of dorsum of hand is loose can be pinched and lifted off.

b. *Dorsal subtendinous space* lies deep to the extensor tendons, between the tendons and the metacarpal bones (Fig. 9.48).

4 *Deep fascia*: The deep fascia is modified at the back of hand to form extensor retinaculum.

**Anatomical Snuffbox**

The anatomical snuffbox (Fig. 9.52a) is a triangular depression on the posterolateral side of the wrist. It is seen best when the thumb is extended.

**Boundaries**

It is bounded anteriorly by tendons of the abductor pollicis longus and extensor pollicis brevis, and posteriorly by the tendon of the extensor pollicis longus. It is limited above by the styloid process of the radius. The floor of the snuffbox is formed by the scaphoid, the trapezium and base of 1st metacarpal.
Contents

The radial artery is deep while the superficial branch of radial nerve and cephalic vein are superficial.

**Competency achievement:** The student should be able to:

**AN 12.14** Identify and describe compartments deep to extensor retinaculum.

**Extensor Retinaculum**

The deep fascia on the back of the wrist is thickened to form the extensor retinaculum which holds the extensor tendons in place. It is an oblique band, directed downwards and medially. It is about 2 cm broad vertically (Fig. 9.52b).

**Attachments**

*Laterally:* Lower part of the sharp *anterior* border of the radius.

*Medially:*
   i. Styloid process of the ulna
   ii. Triquetral
   iii. Pisiform

**Compartments**

The retinaculum sends down septa which are attached to the longitudinal ridges on the posterior surface of the lower end of radius. In this way, 6 osseofascial compartments are formed on the back of the wrist (see Fig. 2.21b). The structures passing through each compartment, from lateral to the medial side, are listed in Table 9.8 and Fig. 9.53.

Each compartment is lined by a synovial sheath, which is reflected onto the contained tendons.

---

**Fig. 9.52b:** Muscles of the back of forearm

**Fig. 9.52c:** Dissection of back of forearm
**DISSECTION**

Make the incision in the centre of dorsum of hand. Reflect the skin of dorsum of hand till the respective borders. Reflect the skin of dorsum of middle finger on each side. Look for nerves on the back of forearm and hand. These are superficial branch of radial nerve and dorsal branch of ulnar nerve.

The dorsal venous network is the most prominent component of the superficial fascia of dorsum of hand. (Identify the beginning of cephalic and basilic veins by tying a tourniquet on the forearm and exercising the closed fist on oneself.)

The deep fascia at the back of wrist is thickened to form extensor retinaculum. Define its margins and attachments. Identify the structures traversing its six compartments.

Clear the deep fascia over the back of forearm. Define the attachment of triceps brachii muscle on the olecranon process of ulna. Define the attachments of the seven superficial muscles of the back of the forearm.

Separate the anterolateral muscles, i.e. brachioradialis, extensor carpi radialis longus and brevis from the extensor digitorum lying in the centre and extensor digiti minimi and extensor carpi ulnaris situated on the medial aspect of the wrist (Fig. 9.52b). Anconeus is situated on the posterolateral aspect of the elbow joint. Dissect all these muscles and trace their nerve supply (refer to BDC App).

**Competency achievement:** The student should be able to:

**AN 12.11** Identify, describe and demonstrate important muscle groups of dorsal forearm with attachments, nerve supply and actions.11

**MUSCLES OF BACK OF FOREARM**

**SUPERFICIAL MUSCLES**

There are seven superficial muscles on the back of the forearm:

1. Anconeus
2. Brachioradialis (Fig. 9.52b)
3. Extensor carpi radialis longus
4. Extensor carpi radialis brevis
5. Extensor digitorum (Fig. 9.52c).

6. Extensor digiti minimi (Fig. 9.52b)
7. Extensor carpi ulnaris.

All the seven muscles cross the elbow joint. Most of them take origin (entirely or in part) from the tip of the lateral epicondyle of the humerus.

These muscles with their nerve supply and actions are described in Tables 9.9 and 9.10.

Additional Points

1. The extensor digitorum and extensor indicis pass through the same compartment of the extensor retinaculum, and have a common synovial sheath.

2. The four tendons of the extensor digitorum emerge from underco... (see Fig. 2.22)

3. On the... join the two tendons of the extensor digiti minimi.

4. On the... are variably connected together by three... downwards and laterally. The medial connection is strong; the lateral connection is weakest and may be absent.

5. The four tendons and three inters... space on the dorsum of the hand.

DEEP MUSCLES

Features

These are as follows:

1. Supinator
2. Abductor pollicis longus
3. Extensor pollicis brevis
4. Extensor pollicis longus (see Fig. 2.23)
5. Extensor indicis

In contrast to the superficial muscles, none of the deep muscles crosses the elbow joint. These have been tabulated in Tables 9.11 and 9.12.

Competency achievement: The student should be able to:

AN 12.15 Identify and describe extensor expansion formation.

Dorsal Digital Expansion/Extensor Expansion

The dorsal digital expansion (extensor expansion) is a small triangular aponeurosis (related to each tendon of the extensor digitorum) covering the dorsum of the proximal phalanx. Its base, which is proximal, covers the metacarpophalangeal (MP) joint. The main tendon of the extensor digitorum occupies the central part of the extension, and is separated from the MP joint by a bursa.

The posterolateral corners of the extensor expansion are joined by tendons of the interossei and of lumbrical muscles. The corners are attached to the deep transverse

metacarpal ligament. The points of attachment of the interossei (proximal) and lumbrical (distal) are often called ‘wing tendons’ (Fig. 9.54).

Near the proximal interphalangeal joint, the extensor tendon divides into a central slip and two collateral slips. The central slip is joined by some fibres from the margins of the expansion, crosses the proximal interphalangeal joint, and is inserted on the dorsum of the base of the middle phalanx. The two collateral slips are joined by the remaining thick margin of the extensor expansion. They then join each other and are inserted on the dorsum of the base of the distal phalanx.

At the metacarpophalangeal and interphalangeal joints, the extensor expansion forms the dorsal part of the fibrous capsule of the joints.

The retinacular ligaments (link ligaments) extend from the side of the proximal phalanx, and form its fibrous flexor sheath, to the margins of the extensor expansion to reach the base of the distal phalanx (Fig. 9.54).

![Fig. 9.54: The dorsal digital expansion of right index, middle, ring and little fingers. Note the insertions of the lumbricals and interossei into it](image-url)
The muscles inserted into the dorsal digital expansions of:

- **Index finger**: First dorsal interosseous, second palmar interosseous, first lumbrical, extensor digitorum slip, and extensor indicis (Fig. 9.54).
- **Middle finger**: Second and third dorsal interossei, second lumbrical, extensor digitorum slip.
- **Ring finger**: Fourth dorsal interosseous, third palmar interosseous, third lumbrical and extensor digitorum slip.
- **Little finger**: Fourth palmar interosseous, fourth lumbrical, extensor digitorum slip and extensor digiti minimi.

**DISSECTION**

Separate extensor carpi radialis brevis from extensor digitorum and identify deeply placed supinator muscle.

Just distal to supinator is abductor pollicis longus. Other three muscles: Extensor pollicis longus, extensor pollicis brevis and extensor indicis are present distal to abductor pollicis longus. Identify them all (refer to BDC App).

Competency achievement: The student should be able to:

**AN 12.12** Identify and describe origin, course, relations, branches (or tributaries), termination of important nerves and vessels of back of forearm.

---

**POSTERIOR INTEROSSEOUS NERVE**

**Features**

It is the chief nerve of the back of the forearm. It is a branch of the radial nerve given off in the cubital fossa, just below the level of the lateral epicondyle of the humerus.

**Course**

It begins in cubital fossa. Passes through supinator muscle to reach back of forearm, where it descends downwards. It ends in a pseudoganglion in the 4th compartment of extensor retinaculum.

**Relations**

1. Posterior interosseous nerve leaves the cubital fossa and enters the back of the forearm by passing between the two planes of fibres of the supinator. Within the muscle it winds backwards around the lateral side of the radius (Fig. 9.55).

2. It emerges from the supinator on the back of the forearm. Here it lies between the superficial and deep muscles. At the lower border of the extensor pollicis brevis, it passes deep to the extensor pollicis longus. It then runs on the posterior surface of the interosseous membrane up to the wrist where it enlarges into a pseudoganglion and ends by supplying the wrist and intercarpal joints.

**Branches**

Posterior interosseous nerve gives muscular, articular and sensory branches (Figs 9.56a and b).

**A. Muscular branches**

- Before piercing the supinator, branches are given to the extensor carpi radialis brevis and to the supinator.
- While passing through the supinator, another branch is given to the supinator.
- After emerging from the supinator, the nerve gives three short branches to:
  - The extensor digitorum (Fig. 9.56b).
  - The extensor digiti minimi.
  - The extensor carpi ulnaris.
- It also gives two long branches:
  - A lateral branch supplies the abductor pollicis longus and the extensor pollicis brevis.
  - A medial branch supplies the extensor pollicis longus and the extensor indicis.

**B. Articular branches**: Articular branches are given to:

- The wrist joint.
- The distal radioulnar joint.
- Intercarpal and intermetacarpal joints.

**C. Sensory branches**: Sensory branches are given to the interosseous membrane, the radius and the ulna.
Deep terminal branch of radial nerve/posterior interosseous nerve and posterior interosseous artery:

Identify the posterior interosseous nerve at the distal border of exposed supinator muscle. Trace its branches to the various muscles.

Look for the radial nerve in the lower lateral part of front of arm between the brachioradialis, extensor carpi radialis longus laterally and brachialis muscle medially. Trace the two divisions of this nerve in the lateral part of the cubital fossa. The deep branch (posterior interosseous nerve) traverses between the two planes of supinator muscle and reaches the back of the forearm where it is already identified.

The nerve runs amongst the muscles of the back of the forearm, and ends at the level of the wrist in a pseudoganglion (Fig. 9.55).

This nerve is accompanied by posterior interosseous artery distal to the supinator muscle. This artery is supplemented by anterior interosseous artery in lower one-fourth of the forearm.

Figs 9.56a and b: Branches of the posterior interosseous nerve

POSTERIOR INTEROSSEOUS ARTERY

Course

Posterior interosseous artery is the smaller terminal branch of the common interosseous, given off in the cubital fossa. It enters the back of the forearm and lies in between the muscles there.

It terminates by anastomosing with the anterior interosseous artery.

Relations

1. It is the smaller terminal branch of the common interosseous artery in the cubital fossa.
2. It enters the back of the forearm by passing between the oblique cord and the upper margin of the interosseous membrane (Fig. 9.55).
3. It appears on the back of the forearm in the interval between the supinator and the abductor pollicis longus and thereafter accompanies the posterior interosseous nerve. At the lower border of the extensor indicis, the artery becomes markedly reduced and ends by anastomosing with the anterior interosseous artery which reaches the posterior compartment by piercing the interosseous membrane at the upper border of the pronator quadratus. Thus
in its lower one-fourth, the back of the forearm is supplied by the anterior interosseous artery.

4 The posterior interosseous artery gives off an interosseous recurrent branch which runs upwards and takes part in the anastomosis on the back of the lateral epicondyle of the humerus (see Fig. 8.10).

ARCHES OF HAND

Hand like foot also has arches. The daily tasks are helped by these arches. The arches are:
i. Proximal transverse arch formed by the two rows of carpal bones.
ii. Distal transverse arch formed by distal ends of metacarpal bones (Fig. 9.57).
   2nd and 3rd carpometacarpal joints are immobile and have zero degree of freedom. 4th has some movement, 5th carpometacarpal joint is a saddle joint with good amount of movement, i.e. flexion/extension; abduction/adduction and opposition.
iii. Longitudinal arch runs along the length of the hand. 2nd and 3rd metacarpal bones form the keystone of the arches. As these are the fixed bones. 1st, 4th and 5th metacarpal bones fold on the sides of 2nd and 3rd metacarpal bones. These arches form concave base for better prehensile activities. Arches are maintained by palmar aponeurosis, palmar metacarpal ligaments, muscles of thenar and hypothenar eminences, long flexor tendons and dorsal interossei.

Palmar arches permit palm and digits to hold the objects firmly. Opponens digit minimi can flex and rotate 5th metacarpal along its long axis. Stability of 2nd and 3rd carpometacarpal joints is a functional adaptation to improve actions of flexor carpi radialis, extensor carpi radialis longus and extensor carpi radialis brevis.

Mnemonics

Anterior forearm muscles: Superficial group “Pretti Found Pamela for Fight”
- Pronator teres
- Flexor carpi radialis
- Palmaris longus
- Flexor carpi ulnaris
- Flexor digitorum superficialis

Interossei muscles: Actions of dorsal vs. palmar in hand “PAd and DAb”

Fig. 9.57: Arches of the hand
The Palmar Adduct and the Dorsal Abd.  
– Use your hand to dab with a pad.

**Median nerve: Hand muscles innervated “The LOAF muscles”**

- Lumbricals 1 and 2
- Opponens pollicis
- Abductor pollicis brevis
- Flexor pollicis brevis

**Radial nerve: Muscles supplied (simplified)**

- “BEST muscles”
- Brachioradialis
- Extensors of wrist metacarpophalangeal and ‘interphalangeal joints’
- Supinator, anconeus
- Triceps brachii

**Lumbricals action**

Lumbricals action is to hold a pea, that is to flex the metacarpophalangeal joints and extend the interphalangeal joints. When one looks at hand in this position, one can see this makes an “L” shape, since L is for Lumbrical.

**Brachioradialis: Function, innervation, one relation, on attachment**

- **Function:** It’s the Beer Raising muscle, flexes elbow, strongest when wrist is oriented like holding a beer mug.
- **Innervation:** Breaks Rule: It’s a flexor muscle. But **Radial** (Radial nerve usually is for extensors) supplies it **BEST** rule: B was for brachioradialis.
- **Important relation:** Behind it is the Radial nerve in the cubital fossa.
- **Attachment:** Attaches to Bottom of Radius.

**Elbow: Which side has common flexor origin**

- **FM (as in FM Radio)**
- Flexor Medial, so Common Flexor Origin is on the medial side.

**CLINICOANATOMICAL PROBLEMS**

**Case 1**

A young man practising tennis complained of severe pain over lateral part of his right elbow. The pain was pin-pointed over his lateral epicondyle.

- **Why does pain occur over lateral epicondyle during tennis games?**
- **Which other games can cause similar pain?**

**Ans:** The pain is due to lateral epicondylitis, also called **tennis elbow**. This is due to repeated microtrauma to the common extensor origin of extensor muscles of the forearm. It can also occur in swimming, gymnastics, basketball, table tennis, i.e. any sport which involves strenuous use of the extensors of the forearm. It may be a degenerative condition.

**Case 2**

A 55-year-old woman complained of abnormal sensations in her right thumb, index, middle and part of ring fingers. Her pain increased during night. There was weakness of her thumb movements.

- **Which nerve was affected and where? Name the syndrome.**

**Ans:** Median nerve is affected while it travels deep to the flexor retinaculum. The syndrome is ‘[carpal tunnel syndrome](https://en.wikipedia.org/wiki/Carpal_tunnel_syndrome)’. There are abnormal sensations in lateral 3½ digits, but there is no loss of sensation over lateral two-thirds of palm. The nerve supply of this area is from...
palmar cutaneous branch of median nerve given in the forearm and then it passes superficial to the flexor retinaculum.

**FURTHER READING**

---

**1.** Describe flexor digitorum profundus muscle under following headings: Origin, insertion, nerve supply, actions and special features.

**2.** Discuss the formation, course and branches of superficial and deep palmar arches.

**3.** Write short notes on:
   a. Flexor retinaculum of wrist
   b. Layers of palm with their components
   c. Midpalmar and thenar spaces
   d. Extensor retinaculum of wrist and structures passing in various compartments under the retinaculum
   e. Carpal tunnel syndrome
   f. Wrist drop
   g. Complete claw hand

---

**Multiple Choice Questions**

1. Which of the following nerves leads to wrist drop?
   a. Ulnar    
   b. Radial    
   c. Median
   d. Musculocutaneous

2. Which nerve supplies adductor pollicis?
   a. Median
   b. Radial
   c. Superficial branch of ulnar
   d. Deep branch of ulnar

3. Which of the following is the action of dorsal interosseous?
   a. Abduction of fingers
   b. Flexion of thumb
   c. Adduction of fingers
   d. Extension of metacarpophalangeal joints

4. Which of the following muscles is not supplied by median nerve?
   a. Abductor pollicis brevis
   b. Flexor pollicis brevis
   c. Opponens pollicis
   d. Adductor pollicis

5. Which of the following nerves is involved in carpal tunnel syndrome?
   a. Ulnar
   b. Median
   c. Radial
   d. Musculocutaneous

6. Which of the following structures does not pass through the carpal tunnel?
   a. Palmar cutaneous branch of median nerve
   b. Median nerve
   c. Tendons of flexor digitorum profundus
   d. Tendon of flexor pollicis longus

7. Superficial cut only on the flexor retinaculum of wrist would damage all structures, except: 
   a. Median nerve
   b. Palmar cutaneous branch of median nerve
   c. Palmar cutaneous branch of ulnar nerve
   d. Ulnar nerve
Upper Limb

8. All the following structures are present in the carpal tunnel, except:
   - a. Tendon of palmaris longus
   - b. Tendon of flexor pollicis longus
   - c. Tendons of flexor digitorum profundus
   - d. Median nerve

9. Compression of median nerve within carpal tunnel causes inability to:
   - a. Flex the interphalangeal joint of thumb
   - b. Extend the interphalangeal joint of thumb

10. de Quervain’s disease affects:
   - a. Tendons of abductor pollicis longus and abductor pollicis brevis
   - b. Tendons of abductor pollicis longus and extensor pollicis brevis
   - c. Tendons of extensor carpi radialis longus and extensor carpi radialis brevis
   - d. Tendons of flexor pollicis longus and flexor pollicis brevis

Answers

Viva voce

- Name the superficial muscles of front of forearm. Name their nerve supply.
- How many deep muscles are there in front of forearm? Which nerve innervates them?
- Where is the origin of lumbrical muscles? How many are unipennate and how many are bipennate muscles? How are the lumbricals innervated?
- Name the branches of radial artery in forearm, wrist and palm.
- Name the branches of ulnar artery in forearm and palm.
- What are the branches of common interosseous artery?
- Which is the most important nerve of the front of forearm?
- Which nerve supplies maximum muscles in the palm? Name these muscles.
- Why does ‘carpal tunnel syndrome’ occur and what are its symptoms?
- What are the attachments of flexor retinaculum? Name structures passing superficial to the retinaculum.
- Show the actions of palmar interossei and dorsal interossei muscles.
- Name the boundaries and contents of ‘anatomical snuffbox’.
- Which is the common site of injury to ulnar nerve?
- What is ape-/monkey-like deformity of thumb?
- Name the attachments of extensor retinaculum of thumb.
- How many compartments are there under extensor retinaculum of wrist? Enumerate their contents?
- Name the muscles supplied by posterior interosseous/deep branch of radial nerve. 
INTRODUCTION

Joints are sites where two or more bones or cartilages articulate. Free movements occur at the synovial joints. Shoulder joint is the most freely mobile joint. Shoulder joint gets excessive mobility at the cost of its own stability, since both are not feasible to the same degree. The carrying angle in relation to elbow joint is to facilitate carrying objects like buckets without hitting the pelvis.

Supination and pronation are basic movements for the survival of human being. During pronation, the food is picked and by supination it is put at the right place—the mouth. While ‘giving’, one pronates, while ‘getting’ one supinates.

The first carpometacarpal joint allows movements of opposition of thumb with the fingers for picking up or holding things. Thumb is the most important digit. Remember Guru Dronacharya asked Eklavya to give his right thumb as Guru-Dakshina, so that he is not able to outsmart Arjuna in archery.

SHOULDER GIRDLE

The shoulder girdle connects the upper limb to the axial skeleton. It consists of the clavicle and the scapula. Anteriorly, the clavicle reaches the sternum and articulates with it at the sternoclavicular joint. The clavicle and the scapula are united to each other at the acromioclavicular joint. The clavicle is a membrane bone. The surface is convex from above downwards and slightly concave from front to back. The sternal surface is smaller than the clavicular surface. It has a reciprocal convexity and concavity. Because of the concavoconvex shape of the articular surfaces, the joint can be classified as a saddle joint.

The sternoclavicular joint is a synovial joint. It is a compound joint as there are three elements taking part in it; namely the medial end of the clavicle, the clavicular notch of the manubrium sterni, and the upper surface of the first costal cartilage. It is a complex joint as its cavity is subdivided into two compartments—superomedial and inferolateral by an intra-articular disc (Fig. 10.1).

The articular surface of the clavicle is covered with fibrocartilage (as the clavicle is a membrane bone). The surface is convex from above downwards and slightly concave from front to back. The sternal surface is smaller than the clavicular surface. It has a reciprocal convexity and concavity. Because of the concavoconvex shape of the articular surfaces, the joint can be classified as a saddle joint.

The capsular ligament is attached laterally to the margins of the clavicular articular surface; and medially to the margins of the articular areas on the sternum and on the first costal cartilage. It is strong anteriorly and posteriorly where it constitutes the anterior and posterior sternoclavicular ligaments.

However, the main bond of union at this joint is the articular disc. The disc is placed laterally to the clavicle on a rough area above and posterior to the articular area for the sternum. Inferiorly, the disc is placed to the sternum and to the first costal cartilage at their junction. Anteriorly and posteriorly, the disc fuses with the capsule.

There are two other ligaments associated with this joint. The interclavicular ligament passes between the sternal ends of the right and left clavicles, some of its fibres being attached to the upper border of the manubrium sterni (Fig. 10.1).
The costoclavicular ligament is attached above to the rough area on the inferior aspect of the medial end of the clavicle. Inferiorly, it is attached to the first costal cartilage and to the first rib. It consists of anterior and posterior laminae.

**Blood supply:** Internal thoracic and suprascapular arteries.

**Nerve supply:** Medial supraclavicular nerve.

**Movements:** Movements of the sternoclavicular joint can be best understood by visualizing the movement at the lateral end of clavicle. These movements are elevation/depression, protraction/retraction and anterior and posterior rotation of the clavicle. The anterior and posterior rotation of clavicle is utilized in overhead movements of the shoulder girdle.

**DISSECTION**

Remove the subclavius muscle from first rib at its attachment with its costal cartilage. Identify the costoclavicular ligament.

Define the sternoclavicular joint and clean the anterior and superior surfaces of the capsule of this joint. Cut carefully through the joint to expose the intra-articular disc positioned between the clavicle and the sternum. The fibrocartilaginous disc divides the joint cavity into a superomedial and an inferolateral compartments.

---

**ACROMIOCLAVICULAR JOINT**

**Features**

The acromioclavicular joint is a plane synovial joint. It is formed by articulation of small facets present:

i. At the lateral end of the clavicle.

ii. On the medial margin of the acromion process of the scapula.

The facets are covered with fibrocartilage. The cavity of the joint is subdivided by an articular disc which may have perforation in it (Fig. 10.1).

The bones are held together by a fibrous capsule and by the articular disc. However, the main bond of union between the scapula and the clavicle is the coracoclavicular ligament described below (Fig. 10.1).

**Blood supply:** Suprascapular and thoracoacromial arteries.

**Nerve supply:** Lateral supraclavicular nerve.

**Movements:** See movements of shoulder girdle.

**Coracoclavicular Ligament**

The ligament consists of two parts—conoid and trapezoid. The trapezoid part is attached, below to the upper surface of the coracoid process; and above to the trapezoid line on the inferior surface of the lateral part of the clavicle. The conoid part is attached, below to the root of the coracoid process just lateral to the scapular notch. It is attached above to the inferior surface of the clavicle on the conoid tubercle.

**Movements of the Shoulder Girdle**

Movements at the two joints of the girdle are always associated with the movements of the scapula (Figs 10.2a to f). The movements of the scapula may or may not be associated with the movements of the shoulder joint. The various movements of shoulder girdle are described below.

a. **Elevation** of the scapula (as in shrugging the shoulders). The movement is brought about by the upper fibres of the trapezius and by the levator scapulae.

   It is associated with the elevation of the lateral end, and depression of the medial end of the clavicle. The clavicle moves around an anteroposterior axis formed by the costoclavicular ligament (Fig. 10.2a).
b. **Depression** of the scapula (drooping of the shoulder). It is brought about by gravity, and actively by the lower fibres of the serratus anterior and by the pectoralis minor.

It is associated with the depression of the lateral end, and elevation of the medial end of the clavicle (Fig. 10.2b). Movements (a) and (b) occur in inferolateral compartment.

c. **Protraction** of the scapula (as in pushing and punching movements). It is brought about by the serratus anterior and by the pectoralis minor (Fig. 10.2c).

It is associated with forward movements of the lateral end and backward movement of the medial end of the clavicle (Fig. 10.2c).

d. **Retraction** of the scapula (squaring the shoulders) is brought about by the rhomboids and by the middle fibres of the trapezius.

It is associated with backward movement of the lateral end and forward movement of the medial end of the clavicle (Fig. 10.2d).

Movements (c) and (d) occur in superomedial compartment.

e. **Lateral or forward rotation** of the scapula around the chest wall takes place during overhead abduction of the arm. The scapula rotates around the coracoacromial ligaments. The movement is brought about by the upper and lower fibres of the trapezius and the lower fibres of the serratus anterior. This movement is associated with rotation of the clavicle around its long axis (Fig. 10.2e).

f. **Medial or backward rotation** of the scapula occurs under the influence of gravity, although it can be brought about actively by the levator scapulae and the rhomboids (Fig. 10.2f).

Movements (e) and (f) occur in inferolateral compartment.

### Ligaments of the Scapula

The **coracoacromial ligament** (see Fig. 6.7): It is a triangular ligament, the apex of which is attached to the tip of the acromion process, and the base to the lateral border of the coracoid process.

The acromion process, the coracoacromial ligament and the coracoid process, together form the **coracoacromial arch**, which is known as the secondary socket for the head of the humerus. It adds to the stability of the joint and protects the head of the humerus.
The suprascapular ligament: It converts the scapular notch into a foramen. The suprascapular nerve passes below the ligament, and the suprascapular artery and vein above the ligament (Fig. 10.3).

The spinoglenoid ligament: It is a weak band which bridges the spinoglenoid notch. The suprascapular nerve and vessels pass beneath the arch to enter the infraspinous fossa (Fig. 10.3).

DISSECTION

Remove the muscles attached to the lateral end of clavicle and acromial process of scapula. Define the articular capsule surrounding the joint. Cut through the capsule to identify the intra-articular disc. Look for the strong coracoacromial ligament.

Competency achievement: The student should be able to:
AN 10.12 Describe and demonstrate shoulder joint for—type, articular surfaces, capsule, synovial membrane, ligaments, relations, movements, muscles involved, blood supply, nerve supply and applied anatomy.2

SHOULDER JOINT

Type
The shoulder joint is a synovial joint of ball and socket variety.

The articular surface, ligaments, and bursae related to this important joint are explained below.

Articular Surface
The joint is formed by articulation of the glenoid cavity of scapula and the head of the humerus. Therefore, it is also known as the glenohumeral articulation.

Structurally, it is a weak joint because the glenoid cavity is too small and shallow to hold the head of the humerus in place (the head is four times the size of the glenoid cavity). However, this arrangement permits great mobility. Stability of the joint is maintained by the following factors.

1. The coracoacromial arch or secondary socket for the head of the humerus (see Fig. 6.8).
2. The musculotendinous cuff of the shoulder (see Fig. 6.7).
3. The glenoidal labrum (Latin lip) helps in deepening the glenoid fossa. Stability is also provided by the muscles attaching the humerus to the pectoral girdle, the long head of the biceps brachii, and the long head of the triceps brachii. Atmospheric pressure also stabilises the joint.

Ligaments
1. The capsular ligament: It is very loose and permits free movements. It is least supported inferiorly where dislocations are common. Such a dislocation may damage the closely related axillary nerve (see Fig. 6.8).
   • Medially, the capsule is attached to the scapula beyond the supraglenoid tubercle and the margins of the labrum.
   • Laterally, it is attached to the anatomical neck of the humerus with the following exceptions.
     – Inferiorly, the attachment extends down to the surgical neck (see Figs 2.14a and b).
     – Superiorly, it is deficient for passage of the tendon of the long head of the biceps brachii (Fig. 10.4a).
   • Anteriorly, the capsule is reinforced by supplemental bands called the superior, middle and inferior glenohumeral ligaments (Fig. 10.4b).
   The area between the superior and middle glenohumeral ligament is a point of weakness in the capsule (foramen of Weitbrecht) which is a common site of anterior dislocation of humeral head.
   The capsule is lined with synovial membrane. An extension of this membrane forms a tubular sheath for the tendon of the long head of the biceps brachii.
2. The coracohumeral ligament: It extends from the root of the coracoid process to the neck of the humerus opposite the greater tubercle. It gives strength to the capsule.
3. Transverse humeral ligament: It bridges the upper part of the bicipital groove of the humerus (between the greater and lesser tubercles). The tendon of the long head of the biceps brachii passes deep to the ligament.
4. The glenoidal labrum: It is a fibrocartilaginous rim which covers the margins of the glenoid cavity, thus increasing the depth of the cavity.
**Bursae Related to the Joint**

1. The subacromial (subdeltoid) bursa (see Figs 6.7 and 6.8).
2. The subscapularis bursa—communicates with the joint cavity.
3. The infraspinatus bursa—may communicate with the joint cavity.

The subacromial and the subdeltoid bursae are commonly continuous with each other but may be separate. Collectively they are called the subacromial bursa, which separates the acromion process and the coracoacromial ligaments from the supraspinatus tendon and permits smooth motion. Any failure of this mechanism can lead to inflammatory conditions of the supraspinatus tendon.

**Relations**

- **Superiorly:** Coracoacromial arch, subacromial bursa, supraspinatus and deltoid (Fig. 10.4c).
- ** Inferiorly:** Long head of the triceps brachii, axillary nerves and posterior circumflex humeral artery.
- **Anteriorly:** Subscapularis, coracobrachialis, short head of biceps brachii and deltoid.
- **Posteriorly:** Infraspinatus, teres minor and deltoid.
- **Within the joint:** Tendon of the long head of the biceps brachii.
Blood Supply
1. Anterior circumflex humeral vessels
2. Posterior circumflex humeral vessels
3. Suprascapular vessels
4. Subscapular vessels

Nerve Supply
1. Axillary nerve
2. Musculocutaneous nerve
3. Suprascapular nerve

Movements of Shoulder Joint
The shoulder joint enjoys great freedom of mobility at the cost of stability. There is no other joint in the body which is more mobile than the shoulder joint. This wide range of mobility is due to laxity of its fibrous capsule, and the four times large size of the head of the humerus as compared with the shallow glenoid cavity. The range of movements is further increased by concurrent movements of the shoulder girdle (Figs 10.5 and 10.6).

However, this large range of motion makes glenohumeral joint more susceptible to dislocations, instability, degenerative changes and other painful conditions specially in individuals who perform repetitive overhead motions (cricketers).

Movements of the shoulder joint are considered in relation to the scapula rather than in relation to the sagittal and coronal planes (Fig. 10.5). When the arm is by the side (in the resting position) the glenoid cavity faces almost equally forwards and laterally; and the head of the humerus faces medially and backwards. Keeping these directions in mind, the movements are analysed as follows.

1. Flexion and extension: During flexion, the arm moves forwards and medially, and during extension, the arm moves backwards and laterally. Thus flexion and extension take place in a plane parallel to the surface of the glenoid cavity (Figs 10.6a and b).
2. Abduction and adduction take place at right angles to the plane of flexion and extension, i.e. approximately midway between the sagittal and coronal planes. In abduction, the arm moves anterolaterally away from the trunk. This movement is in the same plane as that of the body of the scapula (Figs 10.6c and d).
3. Medial and lateral rotations are best demonstrated with a midflexed elbow. In this position, the hand is moved medially across the chest either in front or behind the chest in medial rotation, and laterally in lateral rotation of the shoulder joint (Figs 10.6e and f).
4. Circumduction is a combination of different movements as a result of which the hand moves along a circle. The range of any movement depends on the availability of an area of free articular surface on the head of the humerus.

Muscles bringing about movements at shoulder joint are shown in Table 10.1. Abduction has been analysed.

Analysis of the Overhead Movement of the Shoulder
The overhead movements of flexion and abduction of the shoulder are brought about by smooth and coordinate motion at all joints of the shoulder complex: Glenohumeral, sternoclavicular, acromioclavicular, and scapulothoracic. Only glenohumeral joint motion cannot bring about the 180° of movement that takes place in overhead shoulder movements. The scapula contributes to overhead flexion and abduction by rotating upwardly by 50°–60°. The glenohumeral joint contributes 100°–120° of flexion and 90°–120° of abduction to the total 170°–180° of overhead movements. This makes the overall ratio of 2° of motion of shoulder to 1° of scapulothoracic motion and is often referred to as ‘scapulohumeral rhythm’. Thus for every 15° of elevation, 10° occur at shoulder joint and 5° are due to movement of the scapula.

The humeral head undergoes lateral rotation at around 90° of abduction to help clear the greater tubercle under the acromion process. Although deltoid is the main abductor of the shoulder, the rotator muscles, namely the supraspinatus, infraspinatus, teres
Having studied all the muscles at the upper end of the scapula, it is wise to open and peep into the most mobile shoulder joint. Identify the muscles attached to the greater and lesser tubercles of the humerus. Deep to the acromion process look for the subacromial bursa. Identify coracoid process, acromion process and triangular coracoacromial arch binding these two bones together (see Fig. 6.7).

Trace the supraspinatus muscle from supraspinous fossa of scapula to the greater tubercle of the humerus. On its way, it is intimately fused to the capsule of the shoulder joint.

|                    | • Teres minor                            |                            |

Joint. In the same way, tendons of infraspinatus and teres minor also fuse with the posterior part of the capsule.

Inferiorly, trace the tendon of long head of triceps brachii from the infraglenoid tubercle of scapula.

Cut through the subscapularis muscle at the neck of scapula. It also gets fused with the anterior part of capsule of the shoulder joint as it passes to the lesser tubercle of humerus.

Having studied the structures related to shoulder joint, the capsule of the joint is to be opened.

A vertical incision is given in the posterior part of the capsule of the shoulder joint. The arm is rotated medially and laterally. This helps in head of humerus getting separated from the shallow glenoid cavity.

Inside the capsule, the shining tendon of long head of biceps brachii is visible as it traverses the intertubercular sulcus to reach the supraglenoid tubercle of scapula. This tendon also gets continuous with the labrum glenoidale attached to the rim of glenoid cavity.

**CLINICAL ANATOMY**

- The clavicle may be dislocated at either of its ends. At the medial end, it is usually dislocated forwards. Backward dislocation is rare as it is prevented by the costoclavicular ligament.
- The main bond of union between the clavicle and the manubrium is the articular disc. Apart from its attachment to the joint capsule, the disc is also attached above to the medial end of the clavicle, and below to the manubrium. This prevents the sternal end of the clavicle from tilting upwards when the weight of the arm depresses the acromial end (Fig. 10.1).
  - The clavicle dislocates upwards at the acromio-clavicular joint, because the clavicle overrides the acromial process.
  - The weight of the limb is transmitted from the scapula to the clavicle through the coraco-clavicular ligament, and from the clavicle to the sternum through the sternoclavicular joint. Some of the weight also passes to the first rib by the costoclavicular ligament. The clavicle usually fractures between these two ligaments (Fig. 10.1).
  - **Dislocation:** The shoulder joint is more prone to dislocation than any other joint. This is due to laxity of the capsule and the disproportionate area of the articular surfaces. Dislocation usually occurs when the arm is abducted. In this position, the head of the humerus presses against the lower unsupported part of the capsular ligament. Thus almost always the dislocation is primarily subglenoid. Dislocation endangers the axillary nerve which is closely related to the lower part of the joint capsule (see Fig. 2.15).
  - **Optimum attitude:** In order to avoid ankylosis, many diseases of the shoulder joint are treated in
an optimum position of the joint. In this position, the arm is abducted by 45°–90°.

- **Shoulder tip pain**: Irritation of the peritoneum underlying diaphragm from any surrounding pathology causes referred pain in the shoulder. This is so because the phrenic nerve carrying impulses from peritoneum and the supraca
vicular nerves (supplying the skin over the shoulder) both arise from spinal segments C3, C4 (Figs 10.7a and b).

- The shoulder joint is most commonly approached (surgically) from the front. However, for aspiration, the needle may be introduced either anteriorly through the deltopectoral triangle (closer to the deltoid), or laterally just below the acromion process (Fig. 10.8).

- **Frozen shoulder**: This is a common occurrence. Pathologically, the two layers of the synovial membrane become adherent to each other. Clinically, the patient (usually 40–60 years of age) complains of progressively increasing pain in the shoulder, stiffness in the joint and restriction of all movements particularly external rotation, abduction and medial rotation. As the contribution of the glenohumeral joint is reduced, the patient shows altered scapulohumeral rhythm due to excessive use of scapular motion while performing overhead flexion and abduction.

The surrounding muscles show disuse atrophy. The disease is self-limiting and the patient may recover spontaneously in about two years and much earlier by physiotherapy.

- Shoulder joint disease can be excluded, if the patient can raise both his arms above the head and bring the two palms together (Fig. 10.9). Deltoid muscle and axillary nerve are likely to be intact.
Competency achievement: The student should be able to:

**AN 13.3** Identify and describe the type, articular surfaces, capsule, synovial membrane, ligaments, relations, movements, blood and nerve supply of elbow joint, proximal and distal radioulnar joints, wrist joint and first carpometacarpal joint.

### ELBOW JOINT

#### Features

The elbow joint is a hinge variety of synovial joint between the lower end of humerus and the upper ends of radius and ulna bones.

Elbow joint is the term used for humeroradial and humeroulnar joints. The term elbow complex also includes the superior radioulnar joint also.

#### Articular Surfaces

**Upper**

The capitulum and trochlea of the humerus.

The coronoid fossa lies just above the trochlea and is designed in a manner that the coronoid process of ulna fits into it in extreme flexion. Similarly, the radial fossa just above the capitulum allows for radial head fitting in the radial fossa in extreme flexion.

**Lower**

i. Upper surface of the head of the radius articulates with the capitulum.

ii. Trochlear notch of the ulna articulates with the trochlea of the humerus (Fig. 10.10).

The elbow joint is continuous with the superior radioulnar joint. The humeroradial, the humeroulnar and the superior radioulnar joints are together known as cubital articulations.

#### Ligaments

1. **Capsular ligament:** Superiorly, it is attached to the lower end of the humerus in such a way that the capitulum, the trochlea, the radial fossa, the coronoid fossa and the olecranon fossa are intracapsular. Inferomedially, it is attached to the margin of the trochlear notch of the ulna except laterally; inferolaterally, it is attached to the annular ligament of the superior radioulnar joint. The synovial membrane lines the capsule and the fossae, named above.

   The anterior ligament, and the posterior ligament are thickenings of the capsule.

---

**DANCING SHOULDER**

When one flexes the arm at shoulder joint, there is one small point which you must remember; whether it is July or November there is a gamble of two muscles Pectoralis major and Anterior deltoid in the tussles.

To Teres major, Latissimus dorsi was happily married but while extending, these got joined with Posterior deltoid.

In adduction of course, the joint decided a better course. It went off with two majors (Pectoralis major and Teres major),

On the way they stopped for some gazers, The two majors danced with Subscapularis during medial rotation,

Even Anterior deltoid and Latissimus dorsi, soon joined the happy flirtation

If one wants the joint to laterally rotate, then there is difference in the mate. Posterior deltoid dances with Infraspinatus, Even Teres minor comes and triangulates.

When just abduction is desired, Supraspinatus and Mid-deltoid are required.

But if Kapil Dev has to do the bowling come Trapezius and Serratus anterior following.

Small muscles provide stability
Large ones give it mobility
And shoulder joint dances, dances and dances.
1. The ulnar collateral ligament is triangular in shape (Fig. 10.11). Its apex is attached to the medial epicondyle of the humerus, and its base to the ulna. The ligament has thick anterior and posterior bands: These are attached below to the coronoid process and the olecranon process, respectively. Their lower ends are joined to each other by an oblique band which gives attachment to the thinner intermediate fibres of the ligament. The ligament is crossed by the ulnar nerve and it gives origin to the flexor digitorum superficialis. It is closely related to the flexor carpi ulnaris and the triceps brachii.

2. The radial collateral or lateral ligament: It is a fan-shaped band extending from the lateral epicondyle to the annular ligament. It gives origin to the supinator and to the extensor carpi radialis brevis (Fig. 10.12).

Relations
- Anteriorly: Brachialis, median nerve, brachial artery and tendon of biceps brachii.
- Posteriorly: Triceps brachii and anconeus.
- Medially: Ulnar nerve, flexor carpi ulnaris and common flexors.
- Laterally: Supinator, extensor carpi radialis brevis and other common extensors.

Blood Supply
From anastomoses around the elbow joint (see Fig. 8.10).

Nerve Supply
The joint receives branches from the following nerves.
1. Ulnar nerve
2. Median nerve
3. Radial nerve
4. Musculocutaneous nerve through its branch to the brachialis

Movements
1. Flexion is brought about by:
   -i. Brachialis (see Fig. 8.6)
   -ii. Biceps brachii
   -iii. Brachioradialis

Fig. 10.10: The cubital articulations, including the elbow and superior radioulnar joints

Fig. 10.11: The ulnar collateral ligament of the elbow joint showing anterior, posterior and oblique bands

Fig. 10.12: The radial collateral ligament of the elbow joint
Extension is produced by:
  i. Triceps brachii (Fig. 10.13)
  ii. Anconeus

**Carrying Angle**

The transverse axis of the elbow joint is directed medially and downwards. Because of this, the extended forearm is not in straight line with the arm, but makes an angle of about 13° with it. This is known as the carrying angle. The factors responsible for formation of the carrying angle are as follows.

a. The medial flange of the trochlea is 6 mm deeper than the lateral flange.
b. The superior articular surface of the coronoid process of the ulna is placed oblique to the long axis of the bone.

The carrying angle disappears in full flexion of the elbow, and also during pronation of the forearm. The forearm comes into line with the arm in the midprone position, and this is the position in which the hand is mostly used. This arrangement of gradually increasing carrying angle during extension of the elbow increases the precision with which the hand (and objects held in it) can be controlled. The angle is 10°–15° in males (Fig. 10.14a) and more than 15° in females (Fig. 10.14b).

**DISSECTION**

Cut through the muscles arising from the lateral and medial epicondyles of humerus and reflect them distally, if not already done. Also cut through biceps brachii, brachialis and triceps brachii 3 cm proximal to the elbow joint and reflect them distally.

Remove all the muscles fused with the fibrous capsule of the elbow joint and define its attachments (refer to BDC App).

**CLINICAL ANATOMY**

- **Distension** of the elbow joint by an effusion occurs posteriorly because here the capsule is weak and the covering deep fascia is thin. Aspiration is done posteriorly on any side of the olecranon process (Fig. 10.15).
- **Dislocation** of the elbow is usually posterior, and is often associated with fracture of the coronoid process. The triangular relationship between the olecranon process and the two humeral epicondyles is lost (see Fig. 2.17).
- **Subluxation** of the head of the radius (pulled elbow) occurs in children when the forearm is suddenly pulled in pronation. The head of the radius slips out from the annular ligament (see Fig. 2.25).
- **Tennis elbow** occurs in tennis players. Abrupt pronation with fully extended elbow may lead to pain and tenderness over the lateral epicondyle which gives attachment to common extensor origin (Fig. 10.16a). This is possibly due to:
  a. Sprain of radial collateral ligament.
  b. Tearing of fibres of the extensor carpi radialis brevis.
  c. Recent researches have pointed out that it is more of a degenerative condition rather than inflammatory condition.
- **Student’s (miner’s) elbow** is characterised by effusion into the bursa over the subcutaneous posterior surface of the olecranon process. Students during lectures support their head (for sleeping) with their hands with flexed elbows. The bursa on the olecranon process gets inflamed (Fig. 10.16b).
- **Golfer’s elbow** is the microtrauma of medial epicondyle of humerus, occurs commonly in golf players. The common flexor origin undergoes...
repetitive strain and results in a painful condition on the medial side of the elbow (Fig. 10.17).
- If carrying angle (normal is 13°) is more, the condition is cubitus valgus, ulnar nerve may get stretched leading to weakness of intrinsic muscles of hand. If the angle is less, it is called cubitus varus (Fig. 10.18).
- Under optimal position of the elbow: Generally elbow flexion between 30° and 40° is sufficient to perform common activities of daily living such as eating, combing, dressing, etc. Because of this reason even people who have lost terminal flexion or extension after a fracture/trauma are able to accomplish these personal tasks without much problems.
RADIOULNAR JOINTS

Features
The radius and the ulna are joined to each other at the superior and inferior radioulnar joints. These are described in Table 10.2. The radius and ulna are also connected by the interosseous membrane which constitutes middle radioulnar joint (Fig. 10.19).

INTEROSSEOUS MEMBRANE
The interosseous membrane connects the shafts of the radius and ulna. It is attached to the interosseous borders of these bones. The fibres of the membrane run downwards and medially from the radius to ulna (Fig. 10.19). The two bones are also connected by the oblique cord which extends from the tuberosity of the radius to the tuberosity of the ulna. The direction of its fibres is opposite to that in the interosseous membrane.

1. Superiorly, the interosseous membrane begins 2–3 cm below the radial tuberosity. Between the oblique cord and the interosseous membrane, there is a gap for passage of the posterior interosseous vessels to the back of the forearm.

2. Inferiorly, a little above its lower margin, there is an aperture for the passage of the anterior interosseous vessels to the back of the forearm.

The interosseous membrane performs the following functions.

a. It binds the radius and ulna to each other.
b. It provides attachments to many muscles.
c. It transmits forces (including weight) applied to the radius (through the hand) to the ulna. This transmission is necessary as radius is the main bone taking part in the wrist joint, while the ulna is the main bone taking part in the elbow joint (see Fig. 1.2 and Flowchart 1.1).
d. Separates the forearm into flexor and extensor compartments.

SUPINATION AND PRONATION

Supination and pronation are rotatory movements of the forearm/hand around a vertical axis. In a semiflexed elbow, the palm is turned upwards in supination, and downwards in pronation (kings pronate, beggars supinate). The movements are permitted at the superior and inferior radioulnar joints.

During pronation, head of radius spins within annular ligament. As radius with the hand comes medially across the lower part of ulna, the interosseous membrane is spiralled. During supination, the membrane is despiralised.

The vertical axis of movement of the radius passes through the centre of the head of the radius above, and through the ulnar attachment of the articular disc below (Fig. 10.19). However, this axis is not stationary because the lower end of the ulna is not fixed: It moves backwards and laterally during pronation, and forwards and medially during supination. As a result of this movement, the axis (defined above) is displaced laterally in pronation, and medially in supination.

Supination is more powerful than pronation because it is an antigravity movement. Supination movements are responsible for all screwing movements of the hand, e.g. as in tightening nuts and bolts. Morphologically, pronation and supination were evolved for picking up food and taking it to the mouth.

Around $50^\circ$ of supination and $50^\circ$ of pronation are generally required to perform many of the routine activities.

Pronation is brought about chiefly by the pronator quadratus. It is aided by the pronator teres when the movement is rapid and against resistance. Gravity also helps (Fig. 10.21).

Supination is brought about by the supinator muscle and the biceps brachii. Slow supination, with elbow extended, is done by the supinator. Rapid supination with the elbow flexed, and when performed against
resistance, is done mainly by the biceps brachii (Fig. 10.22).

**DISSECTION**

Remove all the muscles covering the adjacent sides of radius, ulna and the intervening interosseous membrane. This will expose the superior and inferior radioulnar joints including the interosseous membrane.

Cut through the annular ligament to see the superior radioulnar joint.

Clean and define the interosseous membrane. Lastly cut through the capsule of inferior radioulnar joint to locate the intra-articular fibrocartilaginous disc of the joint.

Learn the movements of supination and pronation on dry bones and on yourself (refer to BDC App).

**CLINICAL ANATOMY**

**Supination and pronation:** During supination, the radius and ulna are parallel to each other. During pronation, radius crosses over the ulna (Figs 10.23a and b). In synostosis (fusion) of upper end of radius and ulna, pronation is not possible.

**WRIST (RADIOCARPAL) JOINT**

**Type**

Wrist joint is a synovial joint of the ellipsoid variety between lower end of radius and articular disc of inferior radioulnar joint proximally and three lateral bones of proximal row of carpus, i.e. scaphoid, lunate and triquetral distally.
The pisiform does not play a role in the radiocarpal articulation. It is a sesamoid bone acting as a pulley for flexor carpi ulnaris.

**Articular Surfaces**

**Upper**
1. Inferior surface of the lower end of the radius (Fig. 10.24).
2. Articular disc of the inferior radioulnar joint (Fig. 10.24).

**Lower**
1. Scaphoid
2. Lunate
3. Triquetral bones

**Ligaments**
1. The articular capsule surrounds the joint. It is attached above to the lower ends of the radius and ulna, and below to the proximal row of carpal bones. A protrusion of synovial membrane, called the recessus sacciformis, lies in front of the styloid process of the ulna and in front of the articular disc. It is bounded inferiorly by a small meniscus projecting inwards from the ulnar collateral ligament between the styloid process and the triquetral bone. The fibrous capsule is strengthened by the following ligaments.
2. On the palmar aspect, there are two palmar carpal ligaments.
   - The palmar radiocarpal ligament is a broad band. It begins above from the anterior margin of the lower end of the radius and its styloid process, runs downwards and medially, and is attached below to the anterior surfaces of the scaphoid, the lunate and triquetral bones.
   - The palmar ulnocarpal ligament is a rounded fasciculus. It begins above from the base of the styloid process of the ulna and the anterior margin of the articular disc, runs downwards and laterally, and is attached to the lunate and triquetral bones.

Both the palmar carpal ligaments are considered to be intracapsular.

3. On the dorsal aspect of the joint, there is one dorsal radiocarpal ligament. It is weaker than the palmar ligaments. It begins above from the posterior margin of the lower end of the radius, runs downwards and medially, and is attached below to the dorsal surfaces of the scaphoid, lunate and triquetral bones (Fig. 10.25).
4. The radial collateral ligament extends from the tip of the styloid process of the radius to the lateral side of the scaphoid bone. It is related to the radial artery.
5. The ulnar collateral ligament extends from the tip of the styloid process of the ulna to the triquetral and pisiform bones. Both the collateral ligaments are poorly developed.

**Relations**
- **Anterior**: Long flexor tendons with their synovial sheaths, and median nerve (see Fig. 9.7).
- **Posterior**: Extensor tendons of the wrist and fingers with their synovial sheaths (see Figs 9.52b and c).
- **Lateral**: Radial artery (see Fig. 9.33).

**Blood Supply**
Anterior and posterior carpal arches.

**Nerve Supply**
Anterior and posterior interosseous nerves.

---

**Fig. 10.24**: Cavity of wrist, inferior radioulnar, intercarpal and 1st carpometacarpal joints
Movements

Movements at the radiocarpal joints are accompanied by movements at the midcarpal joint. The midcarpal joint is anatomically separate from radiocarpal joint. The joint between the two rows of carpal bones does not have smooth joint line because of multiple small joints. However, it still behaves as a functional unit in all movements of the wrist joint.

In addition to the congruency and the shape of the articular surfaces of radius and carpal bones, the length of the ulna can also affect the amount of motion available at the wrist joint. In the ulnar negative variance, the distal end of ulna is shorter than the radius and vice versa in ulnar positive variance. The wrist joint has the following movements.

1 Flexion: It takes place more at the midcarpal than at the wrist joint. The main flexors are:
   i. Flexor carpi radialis (Figs 10.26a and b)
   ii. Flexor carpi ulnaris
   iii. Palmaris longus.
   The movement is assisted by long flexors of the fingers and thumb (Figs 10.34a and b), and abductor pollicis longus.

2 Extension: It takes place mainly at the wrist joint. The main extensors are:
   i. Extensor carpi radialis longus
   ii. Extensor carpi radialis brevis
   iii. Extensor carpi ulnaris.
   It is assisted by the extensors of the fingers and thumb (Figs 10.27a and b).
3 *Abduction (radial deviation)*: It occurs mainly at the midcarpal joint. The main abductors are:
   i. Flexor carpi radialis
   ii. Extensor carpi radialis longus and extensor carpi radialis brevis
   iii. Abductor pollicis longus and extensor pollicis brevis

4 *Adduction (ulnar deviation)*: It occurs mainly at the wrist joint. The main adductors are:
   i. Flexor carpi ulnaris
   ii. Extensor carpi ulnaris

5 *Circumduction*: The range of flexion is more than that of extension. Similarly, the range of adduction is greater than abduction (due to the shorter styloid process of ulna).

---

**DISSECTION**

Cut through the thenar and hypothenar muscles from their origins and reflect them distally.

Separate the flexor and extensor retinacula of the wrist from the bones.

Cut through flexor and extensor tendons (if not already done) and reflect them distally *(refer to BDC App)*.

Define the capsular attachments and ligaments and relations of the wrist joint.

**CLINICAL ANATOMY**

- The wrist joint and interphalangeal joints are commonly involved in rheumatoid arthritis *(Figs 10.28a and b)*.

- The back of the wrist is the common site for a ganglion. It is a cystic swelling resulting from mucoid degeneration of synovial sheaths around the tendons *(Fig. 10.29)*.

- The wrist joint can be aspirated from the posterior surface between the tendons of the extensor pollicis longus and the extensor digitorum *(Fig. 10.30)*.

- The joint is immobilised in optimum position of 30° dorsiflexion (extension).

- Because of the complex nature of the joint and the multiple articulations, any injury to the ligaments attached to the proximal or the distal row of carpal bones may cause subluxation of the carpals ventrally or dorsally leading to painful condition of the wrist.

---

*Fig. 10.28a and b*: Rheumatoid arthritis leading to deformities

*Fig. 10.29*: Ganglion cyst at the back of wrist

*Fig. 10.30*: Aspiration of the wrist joint
The anterior ligament
4. The posterior ligaments are oblique bands running downwards and medially.

**Relations**
- **Anteriorly**: The joint is covered by the muscles of the thenar eminence (see Fig. 9.22).
- **Posteriorly**: Long and short extensors of the thumb (Figs. 10.32a and b).
- **Medially**: First dorsal interosseous muscle, and the radial artery (passing from the dorsal to the palmar aspect of the hand through the interosseous space).
- **Laterally**: Tendon of the abductor pollicis longus.

**Blood Supply**
Radial vessels supply blood to the synovial membrane and capsule of the joint.

**Nerve Supply**
First digital branch of median nerve supplies the capsule of the joint.

**Movements**
Flexion and extension of the thumb take place in the plane of the palm, and abduction and adduction at right angles to the plane of the palm. In opposition, the thumb crosses the palm and touches other fingers. Flexion is associated with medial rotation, and extension with lateral rotation at the joint.

Circumduction is a combination of different movements mentioned. The following muscles bring about the movements (Figs. 10.31a to e).

1. **Flexion**
   - Flexor pollicis brevis (see Fig. 9.20)
   - Opponens pollicis

2. **Extension**
   - Extensor pollicis brevis (Fig. 10.32a)
   - Extensor pollicis longus (Fig. 10.32b)

3. **Abduction**
   - Abductor pollicis brevis (see Fig. 9.20)
   - Abductor pollicis longus

4. **Adduction**
   - Adductor pollicis (see Fig. 9.22)

5. **Opposition**
   - Opponens pollicis (see Fig. 9.22)
   - Flexor pollicis brevis

The opposition is a sequential movement of abduction, flexion, adduction of the 1st metacarpal with simultaneous rotation. Opposition is unique to human beings and is one of the most important movements of the hand considering that this motion is used in almost all types of gripping actions.

The adductor pollicis and the flexor pollicis longus exert pressure on the opposed fingers.
Out of these, the most important joint with a separate joint cavity is the first carpometacarpal joint. This is the joint of the thumb and a wide variety of functionally useful movements take place here. Identify the distal surface of trapezium and base of first metacarpal bone.

Define the metacarpophalangeal and interphalangeal joints.

For their dissection, remove all the muscles and tendons from the anterior and posterior aspects of any two metacarpophalangeal joints. Define the articular capsule and ligaments. Do the same for proximal and distal interphalangeal joints of one of the fingers and define the ligaments (refer to BDC App).

**DISSECTION**

Define the metacarpophalangeal and interphalangeal joints.

For their dissection, remove all the muscles and tendons from the anterior and posterior aspects of any two metacarpophalangeal joints. Define the articular capsule and ligaments. Do the same for proximal and distal interphalangeal joints of one of the fingers and define the ligaments (refer to BDC App).

**CLINICAL ANATOMY**

- The 1st carpometacarpal joint can undergo degenerative changes with age which is a painful condition of the base of the thumb.

**METACARPOPHALANGEAL JOINTS**

**Type**

Metacarpophalangeal joints are synovial joints of the ellipsoid variety.

**Ligaments**

Each joint has the following ligaments.

1. **Capsular ligament**: This is thick in front and thin behind.

2. **Palmar ligament**: This is a strong fibrocartilaginous plate (volar plate) which replaces the anterior part of the capsule. It is more firmly attached to the phalanx than to the metacarpal. The various palmar ligaments of the metacarpophalangeal joints are joined to one another by the deep transverse metacarpal ligament.

3. **Medial and lateral collateral ligaments**: These are oblique bands placed at the sides of the joint. Each runs downwards and forwards from the head of the metacarpal bone to the base of the phalanx. These are taut in flexion and relaxed in extension.

**Movements at First Joint and Muscles Producing Them**

1. **Flexion**: Flexor pollicis longus and flexor pollicis brevis.

2. **Extension**: Extensor pollicis longus and extensor pollicis brevis (Figs 10.32a and b).

3. **Abduction**: Abductor pollicis brevis (see Fig. 9.20).

4. **Adduction**: Adductor pollicis (see Fig. 9.22).

**Movements at Second to Fifth Joints and Muscles Producing Them**

1. **Flexion**: Interossei and lumbricals (see Figs 9.21 and 9.23).

2. **Extension**: Extensors of the fingers (Fig. 10.27).

3. **Abduction**: Dorsal interossei (see Fig. 9.23).

4. **Adduction**: Palmar interossei (see Fig. 9.23).

5. **Circumduction**: Above muscles in sequence.

**INTERPHALANGEAL JOINTS**

**Type**

Hinge variety of synovial joints (Fig. 10.33).

**Ligaments**

Similar to the metacarpophalangeal joints, that is one palmar fibrocartilaginous ligament and two collateral bands running downwards and forwards.
Upper Limb

Section 1

 Movements at Second to Fifth Digits

1 Flexion: Flexor digitorum superficialis at the proximal interphalangeal joint, and the flexor digitorum profundus at the distal joint (Fig. 10.34).
2 Extension: Interossei and lumbricals (see Figs 9.21 and 9.23).

Segmental Innervation of Movements of Upper Limb

Figures 10.35a to f show the segments of the spinal cord responsible for movements of the various joints of the upper limb.

The proximal muscles of upper limb are supplied by proximal nerve roots forming brachial plexus and distal muscles by the distal or lower nerve roots. In shoulder, abduction is done by muscles supplied by C5 spinal segment and adduction by muscles innervated by C6, C7 spinal segments.

Elbow joint is flexed by C5, C6 and extended by C7, C8 innervated muscles. Supination is caused by muscle innervated by C6 spinal segment even pronation is done through C6 spinal segment.

Extension and flexion of wrist is done through C6, C7 spinal segments. Both the palmar and dorsal interossei are innervated by T1 spinal segment.

The interphalangeal joints also are flexed and extended by same spinal segments, i.e. C7, C8.

Movements at Interphalangeal Joint of Thumb

Flexion: Flexor pollicis longus.
Extension: Extensor pollicis longus.

**Figs 10.32a and b: Extensors of the joints of thumb**

**Fig. 10.33: Joints of the fingers**

**Figs 10.34a and b: (a) Flexor digitorum superficialis, and (b) flexor digitorum profundus**
**Elbow:** Muscles that flex it

Three Bs Bend the Elbow:
- Brachialis
- Biceps—2 heads
- Brachioradialis

**FACTS TO REMEMBER**
- Sternoclavicular joint is a saddle variety of synovial joint. Its cavity is divided into two parts by an articular disc.
- Movements of shoulder girdle help the movements of shoulder joint during 90°–180° abduction.
- Shoulder joint is freely mobile and is vulnerable to dislocation.
- Ulnar nerve lies behind medial epicondyle. It is not a content of the cubital fossa.
- Carrying angle separates the wrist from the hip joint while carrying buckets, etc.
- Biceps brachii is an important supinator of forearm when the elbow is flexed.
- Kings pronate, while beggars supinate.
- Movements of pronation and supination are not occurring at the elbow or wrist joints.
- First carpometacarpal joint is the most important joint as it permits the thumb to oppose the palm/fingers for holding things.
- Shoulder joint commonly dislocates inferiorly.
- Ulnar nerve lies behind medial epicondyle, pressing the nerve cause tingling sensation. That is why the bone is named ‘humerus’.
- Giving is pronation, receiving is supination. Picking up food with digits is pronation, putting it in the mouth is supination.
- Axis of movements of abduction and adduction of fingers is through the centre of the middle finger.

**CLINICOANATOMICAL PROBLEM**

A 70-year-old lady fell on her left forearm. She heard a crack in the wrist. There was swelling and a bend just proximal to wrist with lateral deviation of the hand.
- Which forearm bone is fractured?
- Reason of bend just proximal to wrist.
- What joints can be subluxated?

**Ans:** There is fracture of the distal end of radius. The backward bend just proximal to the wrist is due to the pull of extensor muscles on the distal segment of radius. The inferior radioulnar joint is usually subluxated.

**FURTHER READING**
1. Describe the shoulder joint under the following headings:
   a. Type
   b. Articular surface
   c. Ligaments
   d. Movements with their muscles
   e. Clinical anatomy

2. Tabulate the features of superior and inferior radio-ulnar joints.

3. Write short notes on:
   a. Carrying angle
   b. Movements of the thumb with muscles responsible for these movements.
   c. Movements of wrist. Enumerate the muscles causing these movements.
   d. Movements occurring at the shoulder girdle.
   e. Movements at metacarpophalangeal joint of middle finger with the muscles responsible for them.

---

**Multiple Choice Questions**

1. One of the following muscles is not a medial rotator of the shoulder joint:
   a. Pectoralis major
   b. Teres major
   c. Teres minor
   d. Latissimus dorsi

2. What type of joint is superior radioulnar joint?
   a. Pivot
   b. Saddle
   c. Plane
   d. Hinge

3. First carpometacarpal joint is:
   a. Saddle
   b. Ellipsoid
   c. Hinge
   d. Pivot

4. Articular surface of sternal end of clavicle is covered by:
   a. Fibrocartilage
   b. Hyaline cartilage
   c. Elastic cartilage
   d. None of the above

5. Which of the following joints contains an articular disc?
   a. Sternoclavicular
   b. Superior radioulnar

6. Which of the following muscles causes protraction of scapula?
   a. Serratus anterior
   b. Levator scapulae
   c. Trapezius
   d. Latissimus dorsi

7. Which of the following muscles is supplied by two nerves with different root values?
   a. Flexor pollicis longus
   b. Pronator teres
   c. Flexor digitorum superficialis
   d. Flexor digitorum profundus

8. Trapezius retracts the scapula along with which of the following muscles?
   a. Rhomboids
   b. Latissimus dorsi
   c. Serratus anterior
   d. Levator scapulae

9. Which of the following muscles is flexor, adductor and medial rotator of shoulder joint?
   a. Pectoralis minor
   b. Pectoralis major
   c. Teres minor
   d. Infraspinatus
VIVA VOCE

- What type of joint is sternoclavicular joint?
- Name the ligaments of sternoclavicular joint.
- Where are the attachments of coracoclavicular ligament?
- Name the movements of shoulder girdle.
- Which muscles cause lateral rotation of the shoulder girdle?
- Mark the attachment of capsule of shoulder joint.
- Which tendon is intracapsular in the shoulder joint?
- Which muscles cause abduction and lateral rotation of shoulder joint? Show these movements.
- What type of joint is elbow joint?
- What type of joints are superior and inferior radio-ulnar joints?
- Name the functions of interosseous membrane.
- Name the supinators and pronators of the forearm with their nerve supply.
- Name the movements occurring at the wrist joint.
- Name bones participating in the 1st carpometacarpal joint. Show the movements of this joint.
- How many joint cavities are there amongst the intercarpal, carpometacarpal and intermetacarpal joints?
- Which is the only muscle causing flexion of distal interphalangeal joints of the fingers?
INTRODUCTION
Surface marking is the projection of the deeper structures on the surface. Its importance lies in various medical and surgical procedures.

SURFACE MARKING
The bony landmarks seen in different regions of the upper limb have been described in appropriate sections.

The surface marking of important structures is given in this chapter.

Competency achievement: The student should be able to:

AN 13.7 Identify and demonstrate surface projection of—cephalic and basilic vein, palpation of brachial artery, radial artery; testing of muscles—trapezius, pectoralis major, serratus anterior, latissimus dorsi, deltoid, biceps brachii, brachioradialis.¹

ARTERIES

Axillary Artery
Hold the arm at right angles to the trunk with the palm directed upwards. The artery is then marked as a straight line by joining the following two points.

• Point 1: Midpoint of the clavicle.
• Point 2: At the lower limit of the lateral wall of axilla where the arterial pulsations can be felt in living person (Fig. 11.1).

At its termination, the axillary artery, along with the accompanying nerves, forms a prominence which lies behind another projection caused by the biceps and coracobrachialis.

Brachial Artery
Brachial artery is marked by joining the following two points.

• Point 1: At the lower limit of the lateral wall of the axilla. Here the axillary artery ends and the brachial artery begins (Fig. 11.2).
• **Point 2:** At the level of the neck of the radius medial to the tendon of the biceps brachii (Fig. 11.2).

Thus the artery begins on the medial side of the upper part of the arm, and runs downwards and slightly laterally to end in front of the elbow. At its termination, it bifurcates into the radial and ulnar arteries.

**Radial Artery**

**In the Forearm**

Radial artery is marked by joining the following points.

• **Point 1:** In front of the elbow at the level of the neck of the radius medial to the tendon of the biceps brachii (Fig. 11.3).

• **Point 2:** At the wrist between the anterior border of the radius laterally and the tendon of the flexor carpi radialis medially, where the radial pulse is commonly felt (Fig. 11.3).

Its course is curved with a gentle convexity to the lateral side.

**In the Hand**

Radial artery is marked by joining the following points.

• **Point 1:** Just below the tip of the styloid process of the radius (Fig. 11.4).

• **Point 2:** At the proximal end of the first intermetacarpal space (Fig. 11.4).

In this part of its course, the artery runs obliquely downwards and backwards deep to the tendons of the abductor pollicis longus, the extensor pollicis brevis, and superficial to the lateral ligament of the wrist joint. Thus it passes through the anatomical snuffbox to reach the proximal end of the first intermetacarpal space.

**Deep Palmar Arch**

Deep palmar arch is formed as the direct continuation of the radial artery. It has a slight convexity towards the fingers.

• **Point 3:** At proximal part of 1st dorsal intermetacarpal space (Fig. 11.3).

• **Point 4:** Just distal to hook of hamate (Fig. 11.3).

It is marked by a slightly convex line, 4 cm long, just distal to the hook of the hamate bone (Fig. 11.3).

The deep palmar arch lies 1.2 cm proximal to the superficial palmar arch across the metacarpals, immediately distal to their bases. The deep branch of ulnar nerve lies in its concavity (see Fig. 9.22).

**Ulnar Artery**

Ulnar artery is marked by joining the following three points.

• **Point 1:** In front of the elbow at the level of the neck of the radius medial to the tendon of the biceps brachii (Fig. 11.3).
• **Point 5:** At the junction of the upper one-third and lower two-thirds of the medial border of the forearm (lateral to the ulnar nerve) (Fig. 11.3).

• **Point 6:** Lateral to the pisiform bone (Fig. 11.3).

  Thus the course of the ulnar artery is oblique in its upper one-third, and vertical in its lower two-thirds. The ulnar nerve lies just medial to the ulnar artery in the lower two-thirds of its course. The ulnar artery continues in the palm as the superficial palmar arch.

### Superficial Palmar Arch

Superficial palmar arch is formed by the direct continuation of the ulnar artery, and is marked as a curved line by joining the following points:

- **Point 1:** Just lateral and distal to the pisiform bone (Fig. 11.5).
- **Point 2:** Medial to the hook of the hamate bone (Fig. 11.5).
- **Point 3:** On the distal border of the thenar eminence in line with the cleft between the index and middle fingers (see Figs 9.32 and 11.5).

The convexity of the arch is directed towards the fingers, and its most distal point is situated at the level of the distal border of the fully extended thumb.

### NERVES

#### Axillary Nerve with its Divisions

Axillary nerve is marked as a horizontal line on the deltoïd muscle, 2 cm above the midpoint between the tip of the acromion process and the insertion of the deltoïd (Fig. 11.4).

Intramuscular injections in the deltoïd are given below the middle part of the muscle to avoid injury to the axillary nerve and its accompanying vessels.

#### Musculocutaneous Nerve

Musculocutaneous nerve is marked by joining the following two points.

- **Point 1:** Just lateral to the axillary artery 3 cm proximal to its termination (Fig. 11.1).
- **Point 2:** Lateral to the tendon of the biceps brachii muscle 2 cm above the bend of the elbow. Here it pierces the deep fascia and continues as the lateral cutaneous nerve of the forearm (see Fig. A1.1).

#### Median Nerve

**In the Arm**

Mark the brachial artery. The nerve is then marked lateral to the artery in the upper half, and medial to the artery in the lower half of the arm. The nerve crosses the artery anteriorly in the middle of the arm (Fig. 11.2).

**In the Forearm**

Median nerve is marked by joining the following two points.

- **Point 1:** Medial to the brachial artery at the bend of the elbow (Fig. 11.3).
- **Point 2:** In front of the wrist, over the tendon of the palmaris longus or 1 cm medial to the tendon of the flexor carpi radialis (Fig. 11.3).

#### Radial Nerve

**In the Arm**

Radial nerve is marked by joining the following points.

- **Point 1:** At the lateral wall of the axilla at its lower limit (Figs 11.1 and 11.4).
- **Point 2:** At the junction of the upper one-third and lower two-thirds of a line joining the lateral epicondyle with the insertion of the deltoïd (Fig. 11.4).
- **Point 3:** On the front of the elbow just below the level of the lateral epicondyle 1 cm lateral to the tendon of the biceps brachii (Fig. 11.4).

The first and second points are joined across the back of the arm to mark the oblique course of the radial nerve in the radial (spiral) groove (posterior compartment). The second and third points are joined on the front of the arm to mark the vertical course of the nerve in the anterior compartment.

**In the Forearm**

Superficial branch of radial nerve is marked by joining the following three points.

- **Point 1:** 1 cm lateral to the biceps tendon just below the level of the lateral epicondyle (Fig. 11.3).
- **Point 2:** At the junction of the upper two-thirds and lower one-third of the lateral border of the forearm just lateral to the radial artery (Fig. 11.3).
- **Point 4:** At the anatomical snuffbox (Fig. 11.4).

The nerve is vertical in its course between points one and two. At the second point, it inclines backwards to reach the snuffbox.

The nerve is closely related to the lateral side of the radial artery only in the middle one-third of the forearm.
SURFACE MARKING, RADIOLOGICAL ANATOMY AND COMPARISON OF UPPER AND LOWER LIMBS

Upper Limb

Posterior Interosseous Nerve/
Deep Branch of Radial Nerve

It is marked by joining the following three points.

- **Point 3:** 1 cm lateral to the biceps brachii tendon just below the level of the lateral epicondyle (Fig. 11.4).
- **Point 5:** At the junction of the upper one-third and lower two-thirds of a line joining the middle of the posterior aspect of the head of the radius to the dorsal tubercle at the lower end of the radius or Lister’s tubercle (Fig. 11.4).
- **Point 6:** On the back of the wrist 1 cm medial to the dorsal tubercle (Fig. 11.4).

Posterior interosseous nerve supplies the muscles of posterior aspect of the forearm.

Ulnar Nerve

**In the Arm**

Ulnar nerve is marked by joining the following points.

---

**Fig. 11.5:** Branches of median nerve and ulnar nerve in the palm. Superficial palmar arch is also shown.

**Fig. 11.6:** Cutaneous nerve supply of palm and dorsum of hand.
Upper Limb

Section 1

In the Forearm

Ulnar nerve is marked by joining the following two points.

- **Point 1:** On the back of the base of the medial epicondyle of the humerus (Fig. 11.7).
- **Point 2:** Lateral to the pisiform bone.

In the lower two-thirds of the forearm, the ulnar nerve lies medial to the ulnar artery (Fig. 11.3).

In the Hand

Ulnar nerve lies superficial to the medial part of flexor retinaculum and medial to ulnar vessels where it divides into superficial and deep branches. The superficial branch supplies medial 1½ digits including their nail beds (Fig. 11.7). The deep branch passes backwards between pisiform and hook of hamate to lie in the concavity of the deep palmar arch (Fig. 11.3).

**JOINTS**

**Shoulder Joint**

The anterior margin of the glenoid cavity corresponds to the lower half of the shoulder joint. It is marked by a line 3 cm long drawn downwards from a point just lateral to the tip of the coracoid process. The line is slightly concave laterally.

**Elbow Joint**

The joint line is situated 2 cm below the line joining the two epicondyles, and slopes downwards and medially. This slope is responsible for the carrying angle.

**Wrist Joint**

The joint line is concave downwards, and is marked by joining the styloid processes of the radius and ulna.

**RETINACULA**

**Flexor Retinaculum**

Flexor retinaculum is marked by joining the following four points.

i. Pisiform bone
ii. Tubercle of the scaphoid bone
iii. Hook of the hamate bone (Fig. 11.8)
iv. Crest of the trapezium.
The upper border is obtained by joining the first and second points, and the lower border by joining the third and fourth points. The upper border is concave upwards, and the lower border is concave downwards (see Figs 9.15 and 9.16).

**Extensor Retinaculum**

Extensor retinaculum is an oblique band directed downwards and medially, and is about 2 cm broad (vertically). Laterally, it is attached to the lower salient part of the anterior border of the radius, and medially to the medial side of the carpus (pisiform and triquetral bones) and to the styloid process of the ulna (see Fig. 9.52).

**SYNOVIAL SHEATHS OF THE FLEXOR TENDONS**

**Common Flexor Synovial Sheath (Ulnar Bursa)**

Above the flexor retinaculum (or lower transverse crease of the wrist), it extends into the forearm for about 2.5 cm. Here its medial border corresponds to the lateral edge of the tendon of the flexor carpi ulnaris, and its lateral border corresponds roughly to the tendon of the palmaris longus.

Ulnar bursa becomes narrower behind the flexor retinaculum, and broadens out below it.

Most of it terminates at the level of the upper transverse creases of the palm, but the medial part is continued up to the distal transverse crease of the little finger.

**Synovial Sheaths for the Tendon of Flexor Pollicis Longus (Radial Bursa)**

Radial bursa is a narrow tube which is coextensive with the ulnar bursa in the forearm and wrist. Below the flexor retinaculum, it is continued into the thumb up to its distal crease (see Fig. 9.7).

**Digital Synovial Sheaths**

The synovial sheaths of the flexor tendons of the index, middle and ring fingers extend from the necks of the metacarpal bones (corresponding roughly to the lower transverse crease of the palm) to the bases of the terminal phalanges (see Fig. 9.7).

**Competency achievement:** The student should be able to:

AN 13.5 Identify the bones and joints of upper limb seen in anteroposterior and lateral view radiographs of shoulder region, arm, elbow, forearm and hand.

**RADIOLOGICAL ANATOMY OF UPPER LIMB**

**General Remarks**

In the case of the limbs, plain radiography is mainly required. For complete information, it is always advisable to have anteroposterior (AP) as well as lateral views; and as far as possible radiographs of the opposite limb should be available for comparison. The skeleton, owing to its high radiopacity, forms the most striking feature in plain skiagrams. In general, the following information can be obtained from plain skiagrams of the limbs.

1. **Fractures** are seen as breaks in the surface continuity of the bone. A fracture line is usually irregular and asymmetrical. An epiphyseal line of an incompletely ossified bone, seen as a gap, should not be mistaken for a fracture: It has regular margins, and is bilaterally symmetrical. Supernumerary or accessory bones are also symmetrical.
2. **Dislocations** are seen as deranged or distorted relations between the articular bony surfaces forming a joint.
3. Below the age of 25 years, the age of a person can be determined from the knowledge of ossification of the bones.
4. Certain **deficiency diseases** like rickets and scurvy can be diagnosed.
5. **Infections** (osteomyelitis) and growths (osteoma, osteoclastoma, osteosarcoma, etc.) can be diagnosed. A localised rarefaction of a bone may indicate an infection.
6. **Congenital absence or fusion** of bones can be seen.

**Reading Plain Skiagrams of Limbs**

1. Identify the view of the picture, anteroposterior or lateral. Each view shows a specific shape and arrangement of the bones.
2. Identify all the bones and their different parts visible in the given radiogram. Normal overlapping and ‘end-on’ appearances of bones in different views should be carefully studied.
3. Study the normal relations of the bones forming joints. The articular cartilage is radiolucent and does not cast any shadow. The radiological ‘joint space’ indicates the size of the articular cartilages. Normally, the joint space is about 2–5 mm in adults.
4. Study the various epiphyses visible in young bones and try to determine the age of the person concerned.

**Shoulder**

A. The following are seen in an AP view of the shoulder (Figs 11.9a and b).

1. The upper end of the humerus, including the head, greater and lesser tubercles and intertubercular sulcus.
2. The scapula, including the glenoid cavity, coracoid (seen end-on), acromion process, its lateral, medial and superior borders, and the superior and inferior angles. The suprascapular notch may be seen.
3. The clavicle, except for its medial end.
4. Upper part of the thoracic cage, including the upper ribs.
B. Study the normal appearance of the following joints.
1. **Shoulder joint**: The glenoid cavity articulates only with the lower half of the head of the humerus (when the arm is in the anatomical position). The upper part of the head lies beneath the acromion process. The greater tuberosity forms the lateral most bony point in the shoulder region.
2. **Acromioclavicular joint**.

C. Note the epiphyses, if any, and determine the age with the help of ossifications described with individual bones.

---

**Elbow**

A. Identify the following bones in an AP and lateral views of the elbow (Figs 11.10a and b).
1. The lower end of humerus, including the medial and lateral epicondyles, the medial and lateral supracondylar ridges, trochlea, the capitulum and the olecranon fossa.
2. The upper end of the ulna, including the olecranon and coronoid processes.
3. The upper end of the radius including its head, neck and tuberosity.
B. Study the normal appearance of the following joints in AP view.
1. Elbow joint
2. Superior radioulnar joint
C. Note the olecranon and coronoid processes in a lateral view of the elbow (Figs 11.11a and b).
D. Note the epiphyses (if any) and determine the age with the help of ossifications described with individual bones.

Hand

A. Identify the following bones in an AP skiagram (Figs 11.12a and b).
1. The lower end of the radius with its styloid process.
2. The lower end of the ulna with its styloid process.
3. The eight carpal bones. Note the overlapping of the triquetral and pisiform bones; and of the trapezium with the trapezoid. Also identify the tubercle of the scaphoid and the hook of the hamate.
### COMPARISON OF UPPER AND LOWER LIMBS

<table>
<thead>
<tr>
<th>Upper limb</th>
<th>Lower limb</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>General</strong></td>
<td>Lower limb with long and heavy bones supports and stabilises the body.</td>
</tr>
<tr>
<td>The upper limb is for range and variety of movements.</td>
<td>Lower limb bud rotates medially, so that big toe points medially.</td>
</tr>
<tr>
<td>Thumb assisted by palm and fingers has the power of holding articles.</td>
<td>Nerve supply: Ventral rami of lumbar 2–5 and sacral 1–3 segments of spinal cord. The two gluteal nerves supply glutei.</td>
</tr>
<tr>
<td>Upper limb bud rotates laterally, so that the thumb points laterally.</td>
<td>Sciatic and one of its terminal branches, the tibial nerve supplies the flexor aspect of the limb. The other terminal branch of sciatic nerve, i.e. common peroneal, supplies the extensors of ankle joint (dorsiflexors) through its deep peroneal branch. Its superficial branch supplies the peroneal muscles of the leg.</td>
</tr>
<tr>
<td>Nerve supply: Ventral rami of cervical 5–8 and thoracic 1 segments of spinal cord. Musculocutaneous, median and ulnar nerves supply the flexor aspects of the limb, while the axillary nerve supplies deltoid and radial nerve supplies the triceps brachii (extensor of elbow) and its branch, the posterior interosseous, supplies the extensors of wrist.</td>
<td>Femoral supplies the quadriceps femoris (extensor of knee) while obturator nerve supplies the adductors.</td>
</tr>
</tbody>
</table>

#### Arm

- **Bones**: Humerus is the longest bone of upper limb
- **Joints**: Shoulder joint is a multiaxial joint
- **Muscles**: Anteriorly: Biceps, brachialis and coracobrachialis supplied by musculocutaneous nerve
  - Posteriorly: Triceps brachii supplied by radial nerve
- **Nerves**: Musculocutaneous for anterior compartment of arm. Radial for posterior compartment. Coracobrachialis equivalent to medial compartment of arm also supplied by musculocutaneous nerve (Fig. A1.1)
- **Branches**: Muscular, cutaneous, articular/genicular, vascular and terminal branches
- **Arteries**: Axillary, brachial, profunda (deep) brachii

#### Thigh

- **Bones**: Femur is the longest bone of lower limb and of the body
- **Joints**: Hip joint is a multiaxial joint
- **Muscles**: Posteriorly: Hamstrings supplied by sciatic nerve
  - Anteriorly: Quadriceps by femoral nerve
  - Medially: Adductors by obturator nerve
- **Nerves**: Sciatic nerve for posterior compartment of thigh, femoral nerve for anterior compartment of thigh, obturator nerve for adductor muscles of medial compartment of thigh
- **Branches**: Muscular, cutaneous, articular/genicular, vascular and terminal branches
- **Arteries**: Femoral, popliteal and profunda femoris (deep)

#### Forearm

- **Bones**: Radius: Preaxial bone
  - Ulna: Postaxial bone
- **Joints**: Elbow joint formed by humerus, radius and ulna, communicates with superior radioulnar joint. Forearm is characterised by superior and inferior radioulnar joints. These are both pivot variety of synovial joints permitting rotary movements of pronation and supination, e.g. meant for picking up food and putting it in the mouth (Fig. 10.19)
- **Muscles**: Palmaris longus (see Fig. 9.3a)
  - Flexor digitorum profundus
  - Flexor pollicis longus
  - Flexor digitorum superficialis
  - Flexor carpi ulnaris
  - Flexor carpi radialis
  - Abductor pollicis longus
  - Extensor digitorum
  - Extensor pollicis longus
- **General**: Anterior aspect: Flexors of wrist and pronators of forearm
  - Posterior aspect: Extensors of wrist, and supinator

#### Leg

- **Bones**: Tibia: Preaxial bone
  - Fibula: Postaxial bone
- **Joints**: Knee joint formed by femur, tibia and patella. Fibula does not participate in knee joint. An additional bone (sesamoid) patella makes its appearance. This is an important weight-bearing joint
- **Muscles**: Plantaris
  - Flexor digitorum longus
  - Flexor hallucis longus
  - Soleus and flexor digitorum brevis
  - Gastrocnemius (medial head)
  - Gastrocnemius (lateral head)
  - Tibialis anterior
  - Extensor digitorum longus
  - Extensor hallucis longus
- **General**: Anterior aspect: Dorsiflexors of ankle joint
  - Posterior aspect: Plantar flexors (flexors) of ankle joint
  - Lateral aspect: Evertors of subtalar joint

<td>Popliteal divides into anterior tibial and posterior tibial in the popliteal fossa. Posterior tibial corresponds to ulnar artery</td>
</tr>
<tr>
<td><strong>Bones and joints</strong></td>
<td></td>
</tr>
<tr>
<td>There are eight small carpal bones occupying very small area of the hand. First carpometacarpal joint, i.e. joint between trapezium and base of 1st metacarpal is a unique joint. It is of saddle variety and permits a versatile movement of opposition in addition to other movements. This permits the hand to hold things, e.g. doll, pencil, food, bat, etc. Opponens pollicis is specially for opposition.</td>
<td>Seven big tarsal bones occupying almost half of the foot. There are special joints between talus, calcaneus and navicular, i.e. subtalar and talocalcaneonavicular joints. They permit the movements of inversion and eversion (raising the medial border/lateral border of the foot) for walking on the uneven surfaces. This movement of inversion is similar to supination and of eversion to pronation of forearm. Flexor digitorum accessorius is a distinct muscle to straighten the action of flexor digitorum longus tendons in line with the toes on which these act. Tibialis anterior, tibialis posterior and peroneus longus reach the foot and sole for the movements of inversion (first two) and eversion (last one), respectively.</td>
</tr>
<tr>
<td><strong>Nerves</strong></td>
<td></td>
</tr>
<tr>
<td>Median nerve supplies 5 muscles of hand including 1st and 2nd lumbricals (abductor pollicis brevis, flexor pollicis brevis, opponens pollicis, 1st and 2nd lumbricals) (see Fig. 9.37) Ulnar nerve corresponds to lateral plantar nerve and supplies 15 intrinsic muscles of the hand (see Fig. 9.34)</td>
<td>Medial plantar supplies four muscles of the sole including 1st lumbrical (abductor hallucis, flexor hallucis brevis, flexor digitorum brevis, 1st lumbrical)</td>
</tr>
<tr>
<td><strong>Muscles</strong></td>
<td></td>
</tr>
<tr>
<td>Muscles which enter the palm from forearm, e.g. flexor digitorum superficialis, flexor digitorum profundus, flexor pollicis longus are supplied by the nerves of the forearm. 1st and 2nd lumbricals are unipennate and are supplied by median nerve. 3rd and 4th are bipennate being supplied by deep branch of ulnar nerve. No muscle on dorsum of hand</td>
<td>Muscles which enter the sole from the leg, e.g. flexor digitorum longus, flexor hallucis longus, tibialis posterior, peroneus longus, are supplied by the nerves of the leg. 1st lumbrical is unipennate and is supplied by medial plantar, 2nd–4th are bipennate being supplied by deep branch of lateral plantar nerve. Extensor digitorum brevis present on dorsum of foot.</td>
</tr>
<tr>
<td><strong>Blood vessels</strong></td>
<td></td>
</tr>
<tr>
<td>Radial artery corresponds to anterior tibial while ulnar artery corresponds to posterior tibial artery. Ulnar artery divides into superficial and deep branches. There are two palmar arches—superficial and deep. The superficial arch mainly is formed by ulnar artery and deep arch is formed mainly by the radial artery. Cephalic vein is along the preaxial border. Basilic vein runs along the postaxial border of the limb and terminates in the middle of the arm</td>
<td>Posterior tibial artery divides into medial plantar and lateral plantar arteries. There is only one arch, the plantar arch formed by lateral plantar and dorsalis pedis (continuation of anterior tibial) arteries The great saphenous vein with perforators lies along the preaxial border. The short saphenous vein lies along the postaxial border but it terminates in the popliteal fossa.</td>

INTRODUCTION

The nerves are very important and precious component of our body. This appendix deals with the main nerves of the upper limb. Most of the nerves course through different regions of the upper limb and have been described in parts in the respective regions. In this appendix, the course of the entire nerve from origin to its termination including the branches and clinical aspects has been described briefly (Fig. A1.1a). Arteries of upper limb have been tabulated in Table A1.5. Important clinical terms related to upper limb have been defined and multiple choice questions are given.

MUSCULOCUTANEOUS NERVE

Musculocutaneous nerve is so named as it supplies muscles of front of arm and skin of lateral side of forearm.

Root Value
Ventral rami of C5–C7 segments of spinal cord.

Course
Axilla and Arm
Musculocutaneous nerve is a branch of the lateral cord of brachial plexus, lies lateral to axillary and upper part of brachial artery. It supplies coracobrachialis, pierces the muscle to lie in the intermuscular septum between biceps brachii and brachialis muscles, both of which are supplied by this nerve (see Fig. 8.6 and A1.1).

Forearm
About 2.5 cm above the crease of elbow, it becomes cutaneous by piercing the deep fascia. The nerve is called the lateral cutaneous nerve of forearm which supplies skin of lateral side of forearm both on the front and back.

Branches
Muscular
Coracobrachialis, long head of biceps brachii, short head of biceps brachii, and brachialis (Fig. A1.1).
Cutaneous
Lateral side of forearm (both on the front and the back).
Articular
Elbow joint.
This nerve rarely gets injured.

AXILLARY OR CIRCUMFLEX NERVE

Axillary nerve is called axillary as it runs through the upper part of axilla though it does not supply any structure there. It is called circumflex as it courses around the surgical neck of humerus (see Fig. 6.6) to supply the prominent deltoid muscle.

Root Value
Ventral rami of C5, C6 segments of spinal cord.

Course
Axilla
Axillary or circumflex nerve is the smaller terminal branch of posterior cord seen in the axilla (see Fig. 4.14).

Quadrangular Space
The nerve passes backwards through the quadrangular space (bounded by subscapularis above, teres major below, long head of triceps brachii medially and surgical neck of humerus laterally) (see Fig. 6.11). Here it lies below the capsule of the shoulder joint.

Surgical Neck of Humerus
Then it passes behind the surgical neck of humerus where it divides into anterior and posterior divisions (Fig. A1.1).

**Fig. A1.1:** Brachial plexus and muscular branches of the main nerves

**Branches**

The branches of axillary nerve are presented in Table A1.1.

**Radial Nerve**

Radial nerve is the thickest branch of brachial plexus.

**Root Value**

Ventral rami of C5–C8, T1 segments of spinal cord (see Fig. 4.14).

**Course**

**Axilla**

Radial nerve lies against the muscles forming the posterior wall of axilla, i.e. subscapularis, teres major and
latissimus dorsi. It then lies for a short distance in arm
behind brachial artery. Then it enters in the lower
triangular space between teres major, long head of triceps
brachii and shaft of humerus. It gives two muscular and
one cutaneous branches in the axilla (Fig. A1.1).

**Radial Sulcus**

Radial nerve enters through the lower triangular space
into the radial sulcus, where it lies between the lateral
and medial heads of triceps brachii along with profunda
brachii vessels (see Fig. 6.11). Long and lateral heads form
the roof of the radial sulcus. It leaves the sulcus by
piercing the lateral intermuscular septum. In the sulcus,
it gives three muscular and two cutaneous branches.

**Front of Arm**

The radial nerve descends on the lower and lateral side
of front of arm deep in the interval between brachialis
on medial side and brachioradialis with extensor carpi
radialis longus on the lateral side to reach capitulum
of humerus (see Fig. 8.17).

**Cubital Fossa**

The nerve enters the lateral side of cubital fossa. There
the radial nerve terminates by dividing into superficial
and deep branches.

The deep branch supplies extensor carpi radialis
brevis and supinator. Then it courses between two heads
of supinator to reach back of forearm.

**Front of Forearm**

The superficial branch leaves the cubital fossa to enter
lateral side of front of forearm, accompanied by the
radial vessels in its upper two-thirds (see Fig. 9.10). At
the junction of upper two-thirds and lower one-third,
the superficial branch turns laterally to reach the
posterolateral aspect of forearm.

**Wrist and Dorsum of Hand**

The superficial branch descends till the anatomical
snuffbox to reach dorsal of hand, where it supplies
skin of lateral half of dorsum of hand and lateral
2½ digits till distal interphalangeal joints (see Figs 7.1b
and 9.52a).

**Back of Forearm and Wrist**

The deep branch of radial nerve enters the back of
forearm, where it supplies the muscles mentioned in
Table A1.2b. Lower down it passes through the 4th
compartment under the extensor retinaculum to reach
the back of wrist where it ends in a pseudoganglion,
branches of which supply the neighbouring joints
(see Fig. 9.56).

**Branches of Radial Nerve**

The branches of radial nerve are presented in
Table A1.2a.

Branches of deep division of radial nerve are shown
in Table A1.2b.

Branches of superficial division of radial nerve are shown in Table A1.2c.

**MEDIAN NERVE**

Median nerve is called median as it runs in the median plane of the forearm.

**Root Value**

Ventral rami of C5–C8, T1 segments of spinal cord.

**Course**

**Axilla**

Median nerve is formed by two roots, lateral root from lateral cord (C5, 6, 7) and medial root from medial cord (C8, T1) of brachial plexus. Medial root crosses the axillary artery to join the lateral root. The median nerve runs on the lateral side of axillary artery (see Fig. 8.9).

**Arm**

Median nerve continues to run on the lateral side of brachial artery till the middle of arm, where it crosses in front of the artery, passes anterior to elbow joint to the cubital fossa (see Figs 8.9 and 8.17 and A1.1).

**Cubital Fossa**

Median nerve lies most medial in the cubital fossa. It gives three branches to flexor muscles of the forearm. It leaves the fossa by passing between two heads of pronator teres (see Figs 8.18 and 8.19).

**Forearm**

Median nerve enters the forearm and lies in the centre of forearm. It lies deep to fibrous arch of flexor digitorum superficialis on the flexor digitorum profundus. Adheres to deep surface of flexor digitorum superficialis, leaves the muscle, along its lateral border. Lastly, it is placed deep and lateral to palmaris longus.

**Flexor Retinaculum**

Median nerve lies deep to flexor retinaculum to enter palm (see Fig. 9.10).

**Palm**

Median nerve lies medial to the muscles of thenar eminence, which it supplies. It also gives cutaneous branches to lateral 3½ digits and their nail beds including skin of distal phalanges on their dorsal aspect (see Figs 7.1, 9.12 and 9.41).

**Branches of Median Nerve**

The branches of median nerve are presented in Table A1.3.

**ULNAR NERVE**

Ulnar nerve is named so as it runs along the medial or ulnar side of the upper limb.

**Root Value**

Ventral rami of C8 and T1. It also gets fibres of C7 from the lateral root of median nerve (see Fig. 4.14).

**Course**

**Axilla**

Ulnar nerve lies in the axilla between the axillary vein and axillary artery on a deeper plane.

**Arm**

Ulnar nerve lies medial to brachial artery. Runs downwards with the brachial artery in its proximal part (see Fig. 8.9). At the middle of arm, it pierces the medial intermuscular septum to lie on its back and descends on the back of medial epicondyle of humerus where it can be palpated. Palpation causes tingling sensations (see Fig. 8.13a). That is why humerus is called ‘funny bone’.

**Forearm**

Ulnar nerve enters the forearm by passing between two heads of flexor carpi ulnaris. There it lies on medial part of flexor digitorum profundus. Ulnar nerve is not a content of cubital fossa.

It is accompanied by the ulnar artery in lower two-thirds of forearm (see Fig. 9.10).

It gives two muscular and two cutaneous branches (Table A1.4 and Fig. A1.1).

**Flexor Retinaculum**

Finally, it lies on the medial part of flexor retinaculum to enter palm. At the distal border of retinaculum, the nerve divides into its superficial and deep branches (see Figs 9.13 and 9.15).

**Palm**

Superficial branch supplies palmaris brevis and gives digital branches to medial 1½ digits including medial 1½ nail beds till the distal interphalangeal joints (Fig. A1.2).

Deep branch supplies most of the intrinsic muscles of the hand. At first, it supplies three muscles of hypothenar eminence. Running in the concavity of deep palmar arch, it gives branches to 4th and 3rd lumbricals from deep aspect; 4,3,2,1 dorsal interossei and 4,3,2,1 palmar interossei to end in adductor pollicis (Table A1.5).

Since it supplies intrinsic muscles of hand responsible for finer movements, this nerve is called ‘musician’s nerve’ (see Figs 9.34a and b).

**Branches**

The branches of ulnar nerve are presented in Table A1.4 and Fig. A1.1.

CLINICAL ANATOMY

Musculocutaneous nerve injury

1 and 2: Paralysis of biceps and brachialis
3. Sensory loss on lateral side of forearm

Axillary nerve injury

Loss of abduction from beginning to 90°
Sensory loss over lower half of deltoid—regimental/badge sign.

Radial nerve injury

1. No extension of elbow
2. Wrist drop
3. Sensory loss (Fig. A1.2)
Median nerve injury

1. Weak flexion of wrist
2. Loss of pronation of forearm
3. Loss of flexion of proximal interphalangeal and distal interphalangeal joints of index and middle fingers
4. Loss of flexion at interphalangeal joint of thumb
5. Loss of thenar eminence
6. Sensory, trophic and vasomotor changes (see Figs 9.40 to 9.44 and A1.2)

Ulnar nerve injury

1. Flattening of medial border of forearm
2. Loss of flexion at distal interphalangeal joints of 4th and 5th digits
3. Loss of hypothenar eminence
4. Loss of adduction of thumb
5. Loss of abduction of all fingers except little finger
6. Loss of adduction of 2nd, 4th and 5th digits
7. Slight clawing of 2nd and 3rd digits
8. Marked clawing of 4th and 5th digits
9. Sensory, trophic and vasomotor changes (Fig. A1.2)

- If ulnar nerve is injured at the elbow, the clawing of the fingers is less, because medial half of flexor digitorum profundus (flexor of proximal and distal interphalangeal joints) also gets paralysed. If ulnar nerve is injured at wrist, the clawing of the fingers is more as intact flexor digitorum profundus flexes the digits more. Thus if lesion is proximal (near elbow), clawing is less. On the contrary, if lesion is distal (near wrist), clawing is more. This is called 'action of paradox'/ulnar paradox.
- If both ulnar and median nerves get paralysed, there is complete claw hand (see Fig. 9.45).

Table A1.5 shows the comparison between injuries of median and ulnar nerves at the wrist. Table A1.6 gives the arteries of upper limb with their branches and area of distribution.

Fig. A1.3: Arteries of the upper limb
SYMPATHETIC INNERVATION

1. The sympathetic innervation of the upper limb is derived from the upper six thoracic segments of the spinal cord. The fibres arise from the lateral horn cells and come out with the ventral roots as preganglionic (white rami) fibres. These fibres ascend in the sympathetic chain to their appropriate ganglia for relay.

2. The postganglionic (grey rami) fibres emerge from the middle and inferior cervical and the first thoracic (stellate) sympathetic ganglia, and join the five roots (C5–C8, T1) of the brachial plexus.

3. The blood vessels to the skeletal muscles are dilated by the sympathetic activity. To the skin, however, these nerves are vasomotor, sudomotor and pilomotor.

Competency achievement: The student should be able to:
AN 13.8 Describe development of upper limb.

EMBRYOLOGY OF THE UPPER LIMB

1. The upper limb bud appears on the ventrolateral aspect of the body wall opposite the lower cervical segments, at the end of the fourth week of development. The development of the upper limb precedes that of the lower limb by a few days.

2. Most investigators believe that the muscles of the upper limb develop in situ from the local mesoderm, and do not receive by contribution from the somites.

3. The axis artery of the upper limb develops from the seventh cervical intersegmental artery. In adults, it persists as axillary, brachial and anterior interosseous arteries, and as the deep palmar arch. The other arteries are secondary outgrowth from the axial artery.

4. Limb muscles: Mesenchyme from dorsolateral cells of somites thickens to form muscles. Muscles are derived from several segments. Spinal nerves supply muscles and also provide sensory nerves for dermatomes. Radial nerve is formed by combination of dorsal segmental branches. Ulnar and median nerves are formed by combination of ventral segmental branches.

Molecular Regulation of Limb Development

1. Limb outgrowth in the forelimb is initiated by T-box family 5 (for transcription); brachyury gene for tail growth (TBX 5) and fibroblast growth factor 10 (FGF 10).

2. Positioning of limb along cranio-caudal axis is regulated by homeobox genes (HOX genes).

3. Apical ectodermal ridge formation is induced by bone morphogenetic proteins (BMPs) by signaling through homeobox gene muscle segment homeobox (MSX 2).

4. Patterning of anteroposterior axis of limb is controlled by zone of polarizing activity (ZPA) by secreting retinoic acid (RA) and sonic hedgehog (SHH).

5. Distal growth of the limb is affected by progressive zone, which in turn is maintained by FGF4 and FGF8.

Molecular Regulation of Muscle Development

Lateral plate mesoderm expresses BMP4 and FGFs which with the help of wingless/integrated (WNT) proteins from adjacent ectoderm signal upper lateral cells of dermomyotome to express muscle specific gene muscle differentiation (MyoD).

MyoD and myogenic factor 5 (Myf5) are members of family of transcription factor called myogenic regulatory factors (MRFs). These activate pathways for muscle development.

Molecular basis for Laterality Sequencing

The molecular basis for laterality sequencing is the accumulation of the signaling molecules, the serotonin [5-hydroxytryptamine (5-HT)], mnx and fibroblast growth factor 8 (FGF8) on left side and monoamine oxidase (MAO) on right side. The paired like homeo-domain 2 (PTX2) is the master gene for left sidedness.

CLINICAL TERMS

Shoulder joint may be dislocated inferiorly: The shoulder joint is surrounded by short muscles on all aspects except inferiorly. Since the joint is quite mobile, it dislocates at the unprotected site, i.e. inferiorly (see Fig. 2.18).

Student’s elbow: Inflammation of the bursa over the insertion of triceps brachii is called student’s elbow. It is common in students as they use the flexed elbow to support the head while attempting hard to listen to the lectures in between their ‘naps’ (see Fig. 10.16b).

Tennis elbow: Lateral epicondylitis occurs in players of lawn tennis or table tennis. The extensor muscles of forearm are used to hit the ball sharply, causing repeated microtrauma to the lateral epicondyle and its subsequent inflammation (see Fig. 10.16a). It may be a degenerative condition.

Pulled elbow: While pulling the children by their hands (getting them off the bus), the head of radius may slip out of the annular ligament. Annular ligament is not tight in children as in adults, so the head of radius slips out (see Fig. 2.25).

Boxer’s palsy or swimmer’s palsy: Serratus anterior causes the movement of protraction. If the long thoracic nerve is injured, the muscle gets paralysed,
seen as ‘winging of scapula’ (see Fig. 2.12). Such a person cannot hit his opponent by that hand. Neither can he make strokes while swimming.

**Golfer’s elbow/medial epicondylitis**: Occurs in golf players. Repeated microtrauma to medial epicondyles causes inflammation of common flexor origin and pain in flexing the wrist (see Fig. 10.17).

**Waiter’s tip or policeman’s tip**: ‘Taking the tip quietly’ Erb–Duchenne paralysis occurs due to involvement of Erb’s point. At Erb’s point, C5, C6 roots join to form upper trunk, two divisions of the trunk arise and two branches, the suprascapular and nerve to subclavius also arise (see Fig. 4.16).

**Wrist drop**: Paralysis of radial nerve in axilla or radial sulcus or anterolateral side of lower part of arm or paralysis of its deep branch in cubital fossa leads to wrist drop (see Fig. 8.25).

**Carpal tunnel syndrome**: Median nerve gets compressed under the flexor retinaculum, leading to paralysis of muscles of thenar eminence. It is called ‘ape-like or monkey-like hand’. There is loss of sensation in lateral 3½ digits including nail beds. Median nerve is the ‘eye of the hand’. There is little clawing of index and middle fingers also (see Figs 9.40 to 9.44).

**Cubital tunnel syndrome**: Ulnar nerve gets entrapped between two heads of flexor carpi ulnaris muscle, leading to paralysis of muscles of thenar eminence, all interossei and adductor pollicis and 3rd and 4th lumbricals. There is clawing of medial two digits, gutters in the hand and loss of hypothenar eminence (see Figs 9.35 and 9.36).

**Volkmann’s ischaemic contracture**: This condition occurs due to fibrosis of the muscles of the forearm, chiefly the flexors. It usually occurs with injury to the brachial artery in supracondylar fractures of humerus (see Fig. 2.16b).

**Dupuytren’s contracture**: This clinical condition is due to fibrosis of medial part of palmar aponeurosis especially the part reaching the ring and little fingers. The fibrous bands are attached to proximal and middle phalanges and not to distal phalanges. So proximal and middle phalanges are flexed, while distal phalanges remain extended (see Fig. 9.18).

**Funny bone**: Ulnar nerve is palpable in flexed elbow behind the medial epicondyly. Palpating the nerve gives rise to funny sensations in the medial side of forearm. Since medial epicondyly is part of humerus, it is called humerus or funny bone (see Fig. 2.15).

**Pointing finger**: Branch of anterior interosseous nerve to lateral half of flexor digitorum profundus is injured in the middle of the forearm. The index finger is affected the most. It remains extended and keeps pointing forwards (despite the fact that remaining three fingers are pointing towards self) (see Fig. 9.39).

**Complete claw hand**: Complete claw hand is due to injury of lower trunk of brachial plexus especially the root, which supplies intrinsic muscles of hand. The injury is called ‘Klumpke’s paralysis’. The metacarpophalangeal joints are extended while both the interphalangeal joints of all fingers are actually flexed (see Fig. 9.45).

**Breast**: The breast is a frequent site of carcinoma (cancer). Several anatomical facts are of importance in diagnosis and treatment of this condition. Abscesses may also form in the breast and may require drainage. The following facts are worthy to note.

Incisions into the breast are usually made radially to avoid cutting the lactiferous ducts (see Fig. 3.9). Cancer cells may infiltrate the suspensory ligaments. The breast then becomes fixed. Contraction of the ligaments can cause retraction or puckering (folding) of the skin.

Infiltration of lactiferous ducts and their consequent fibrosis can cause retraction of the skin.

Obstruction of superficial lymph vessels by cancer cells may produce oedema of the skin giving rise to an appearance like that of the skin of an orange (peau d’orange appearance) (see Fig. 3.16).

Because of bilateral communications of the lymphatics of the breast across the midline, cancer may spread from one breast to the other (see Fig. 3.17).

Because of communications of the lymph vessels with those in the abdomen, cancer of the breast may spread to the liver. Cancer cells may ‘drop’ into the pelvis especially ovary (Krukenberg’s tumour) producing secondaries there (see Fig. 3.17).

Apart from the lymphatics, cancer may spread through the veins. In this connection, it is important to know that the veins draining the breast communicate with the vertebral venous plexus of veins. Through these communications, cancer can spread to the vertebrae and to the brain (see Fig. 3.17).

**Ligaments of Cooper**: Fibrous strands extending between skin overlying the breast and the underlying pectoral muscles. These support the gland.

**Montgomery’s glands**: Glands beneath the areola of mammary gland.

**Subareolar plexus of Sappey**: Lymphatic plexus beneath the areola of the breast.

**Blood pressure**: The blood pressure is universally recorded by auscultating the brachial artery on the anteromedial aspect of the elbow joint (see Fig. 8.11).
Intravenous injection: The median cubital vein is the vein of choice for intravenous injections, for withdrawing blood from donors, and for cardiac catheterisation, because it is fixed by the perforator and does not slip away during piercing (see Fig. 7.8).

Intramuscular injection: Intramuscular injections are often given into the deltoid. They should be given in the middle of the muscle to avoid injury to the axillary nerve (see Fig. 6.9).

Radial pulse: The radial artery is used for feeling the (arterial) pulse at the wrist. The pulsation can be felt well in this situation because of the presence of the flat radius behind the artery (see Fig. 9.10).

Lister’s tubercle: Dorsal tubercle on lower end of posterior surface of radius. This acts as a pulley for the tendon of extensor pollicis longus (see Fig. 2.20).

de Quervain’s disease is a thickening of sheath around tendons of abductor pollicis longus and extensor pollicis brevis giving rise to pain on lateral side of wrist.

C. If only b and d are correct
D. If only d is correct
E. If all are correct

6. Injury to the median nerve in the arm would affect:
   a. Pronation of the forearm
   b. Flexion of the wrist
   c. Flexion of the thumb
   d. Supination of the forearm

7. Which of the following is/are true regarding humerus?
   a. The head of the humerus commonly dislocates posteriorly.
   b. Common sites of fracture are surgical neck, shaft and supracondylar region
   c. Lower end is the growing end.
   d. Axillary, radial and ulnar nerves are directly related to the bone

8. Clavicle:
   a. Is a long bone
   b. Develops by intramembranous ossification
   c. Is the first bone to ossify
   d. Has a well-developed medullary cavity

9. In Erb’s paralysis:
   a. Abduction and lateral rotation of the arm are lost
   b. Flexion and pronation of the forearm are lost
   c. Biceps and supinator jerks are lost
   d. Sensations are lost over the medial side of the arm

10. Which of the following statements is/are true regarding ‘mammary gland’?
    a. It is modified sweat gland
    b. Lies in superficial fascia
    c. 75% of the lymph from mammary gland drains into axillary lymph nodes
    d. Some lymphatic vessels communicate with the lymph vessels of opposite side

Answers

1. a.–ii,   b.–iii,   c.–iv,   d.–i
2. a.–iii,   b.–ii,   c.–i
3. a.–ii,   b.–i,   c.–iv,   d.–ii
4. a.–iii,   b.–iv,   c.–ii,   d.–i
5. a.–ii,   b.–iv,   c.–iii,   d.–i
6. A
7. C
8. A
9. B
10. E.
1. a. Identify the muscle.
   b. Name its nerve supply.

2. a. Identify the cord of brachial plexus.
   b. Enumerate its branches.

3. a. Identify the muscle.
   b. Name its heads.

4. a. Identify the area.
   b. Name its contents in order.

5. a. Identify the nerve.
   b. Name its muscular branches in the palm.

6. a. Identify the joint.
   b. Name its movements.

7. a. Identify the structure on right middle finger.
   b. Name the muscles inserted.

8. a. Identify the structure.
   b. Name the structures lying on its superficial aspect.

9. a. Identify the structure.
   b. Name the contents of its 4th compartment.

10. a. Identify the muscle.
    b. Name the nerves supplying it.
# Upper Limb

## Answers: Spots on Upper Limb

1. **a.** Pectoralis major  
   **b.** Medial pectoral and lateral pectoral nerves

2. **a.** Medial cord of brachial plexus  
   **b.**  
   - Medial pectoral  
   - Medial cutaneous nerve of arm  
   - Medial cutaneous nerve of forearm  
   - Ulnar nerve  
   - Medial root of median

3. **a.** Biceps brachii  
   **b.** Long head and short head

4. **a.** Cubital fossa  
   **b.**  
   - Median nerve  
   - Brachial artery  
   - Tendon of biceps brachii  
   - Radial nerve

5. **a.** Median nerve  
   **b.**  
   - Flexor pollicis brevis  
   - Abductor pollicis brevis  
   - Opponens pollicis  
   - 1st and 2nd lumbricals

6. **a.** 1st carpometacarpal joint  
   **b.**  
   - Flexion with medial rotation  
   - Extension with lateral rotation  
   - Abduction  
   - Adduction  
   - Opposition

7. **a.** Extensor expansion of right middle finger  
   **b.**  
   - Tendon of extensor digitorum  
   - 2nd lumbrical  
   - 2nd and 3rd dorsal interossei

8. **a.** Flexor retinaculum  
   **b.**  
   - Palmar cutaneous branch of median nerve  
   - Tendon of palmaris longus  
   - Palmar cutaneous branch of ulnar nerve  
   - Ulnar artery  
   - Ulnar nerve

9. **a.** Extensor retinaculum  
   **b.**  
   - Tendon of extensor digitorum  
   - Tendon of extensor indicis  
   - Anterior interosseous artery  
   - Posterior interosseous nerve

10. **a.** Flexor digitorum profundus  
    **b.** Medial half by ulnar nerve and lateral half by anterior interosseous branch of median nerve

Bolo kya—heart, bolo kya—heart
Thorax (Latin chest) forms the upper part of the trunk of the body. It not only permits boarding and lodging of the thoracic viscera, but also provides necessary shelter to some of the abdominal viscera.

The trunk of the body is divided by the diaphragm into an upper part, called the thorax, and a lower part, called the abdomen. The thorax is supported by a skeletal framework, thoracic cage. The thoracic cavity contains the principal organs of respiration—the lungs and of circulation—the heart, both of which are vital for life.

SURFACE LANDMARKS OF THORAX

Bony Landmarks

1. **Suprasternal or jugular notch** (Fig. 12.1): It is felt just above the superior border of the manubrium between the sternal ends of the clavicles. It lies at the level of the lower border of the body of the second thoracic vertebra. The trachea can be palpated in this notch.

2. **Sternal angle/angle of Louis**: It is felt as a transverse ridge about 5 cm below the suprasternal notch. It marks the manubriosternal joint, and lies at the level of the second costal cartilage anteriorly, and the disc between the fourth and fifth thoracic vertebrae posteriorly. This is an important landmark for the following reasons.
   a. The ribs are counted from this level downwards. There is no other reliable point (anteriorly) from which the ribs may be counted. The second costal cartilage and second rib lie at the level of the sternal angle or angle of Louis (French physician 1787–1872). The ribs are counted from here by tracing the finger downwards and laterally (because the lower costal cartilages are crowded and the anterior parts of the intercostal spaces are very narrow).
   b. It marks the plane which separates the superior mediastinum from the inferior mediastinum.
   c. The ascending aorta ends at this level.
   d. The arch of the aorta begins and also ends at this level.
   e. The descending aorta begins at this level.
   f. The trachea divides into two principal bronchi.
   g. The azygos vein arches over the root of the right lung and opens into the superior vena cava.
   h. The pulmonary trunk divides into two pulmonary arteries just below this level.
   i. The thoracic duct crosses from the right to the left side at the level of the fifth thoracic vertebra and reaches the left side at the level of the sternal angle.
   j. It marks the upper limit of the base of the heart.
   k. The cardiac plexuses are situated at the same level.

3. **Xiphisternal joint**: The costal margin on each side is formed by the seventh to tenth costal cartilages. Between the two costal margins, there lies the...
infrasternal or subcostal angle. The depression in the angle is also known as the epigastric fossa.

The xiphoid (Greek sword) process lies in the floor of the epigastric fossa. At the apex of the angle, the xiphisternal joint may be felt as a short transverse ridge. It lies at the level of the upper border of the ninth thoracic vertebra (Fig. 12.1).

4 Costal cartilages: The second costal (Latin rib) cartilage is attached to the sternal angle. The seventh cartilage bounds the upper part of the infrasternal angle. The lateral border of the rectus abdominis or the linea semilunaris joins the costal margin at the tip of the ninth costal cartilage. The tenth costal cartilage forms the lower part of the costal margin (Figs 12.1 and 12.2a).

5 Ribs: The scapula overlies the second to seventh ribs on the posterolateral aspect of the chest wall. The tenth rib is the lowest point, lies at the level of the third lumbar vertebra. Though the eleventh rib is longer than the twelfth, both of them are confined to the back and are not seen from the front (Fig. 12.2b and c).

6 Thoracic vertebral spines: The first prominent spine felt at the lower part of the back of the neck is that of the seventh cervical vertebra or vertebra prominens. Below this spine, all the thoracic spines can be palpated along the posterior median line (Fig. 12.3). The third thoracic spine lies at the level of the roots of the spines of the scapulae. The seventh thoracic spine lies at the level of the inferior angles of the scapulae.

Soft Tissue Landmarks
1 The nipple: The position of the nipple varies considerably in females, but in males it usually lies in the fourth intercostal space about 10 cm from the midsternal line (Fig. 12.4).
2 Apex beat: It is a visible and palpable cardiac impulse in the left fifth intercostal space, 9 cm from the midsternal line, or medial to the midclavicular line.
3 Trachea: It is palpable in the suprasternal notch midway between the two clavicles.
4 Midclavicular: It is a vertical plane passing through the midinguinal point, the tip of the ninth costal cartilage and middle of clavicle (Fig. 12.5).
5 Midaxillary line: It passes vertically between the two folds of the axilla (Fig. 12.5).
6 Scapular line: It passes vertically along the inferior angle of the scapula.

SKELETON OF THORAX
The skeleton of thorax is also known as the thoracic cage. It is an osseocartilaginous elastic cage which is primarily designed for increasing and decreasing the intrathoracic pressure, so that air is sucked into the lungs during inspiration and expelled during expiration.

FORMATION
Anteriorly, by the sternum (Greek chest) (Figs 12.1 and 12.2).
Posteriorly, by the 12 thoracic vertebrae and the intervening intervertebral discs (Fig. 12.3).

On each side, by 12 ribs with their cartilages.

Each rib articulates posteriorly with the vertebral column. Anteriorly, only the upper seven ribs articulate with the sternum through their cartilages and these are called true or vertebrosternal ribs.

The costal cartilages of the next three ribs, i.e. the eighth, ninth and tenth end by joining the next higher costal cartilage. These ribs are, therefore, known as vertebrochondral ribs. The costal cartilages of the seventh, eighth, ninth and tenth ribs form the sloping costal margin.

The anterior ends of the eleventh and twelfth ribs are free: These are called floating or vertebral ribs. The vertebrochondral and vertebral ribs, i.e. the last five ribs, are also called false ribs because they do not articulate with the sternum.

The costovertebral, costotransverse, manubrio-sternal and chondrosternal joints permit movements of the thoracic cage during breathing.

The anterior ends of the eleventh and twelfth ribs are free: These are called floating or vertebral ribs. The vertebrochondral and vertebral ribs, i.e. the last five ribs, are also called false ribs because they do not articulate with the sternum.

The costovertebral, costotransverse, manubrio-sternal and chondrosternal joints permit movements of the thoracic cage during breathing.
SHAPE

The thorax resembles a truncated cone which is narrow above and broad below (Fig. 12.7). The narrow upper end is continuous with the root of the neck from which it is partly separated by the suprapleural membrane or Sibson’s fascia. The broad or lower end is almost completely separated from the abdomen by the diaphragm which is deeply concave downwards. The thoracic cavity is actually much smaller than what it appears to be because the narrow upper part appears broad due to the shoulders, and the lower part is greatly encroached upon by the abdominal cavity due to the upward convexity of the diaphragm.

In transverse section, the thorax is reniform (bean-shaped, or kidney-shaped). The transverse diameter is greater than the anteroposterior diameter. However, in infants below the age of two years, it is circular. In quadrupeds, the anteroposterior diameter is greater than the transverse, as shown in Fig. 12.8.

In infants, the ribs are horizontal and as a result the respiration is purely abdominal by the action of the diaphragm. In adults, the thorax is oval. The ribs are oblique and their movements alternately increase and decrease the diameters of the thorax. This results in the drawing in of air into the thorax called inspiration and its expulsion is called expiration. This is called thoracic respiration. In the adult, we, therefore, have both abdominal and thoracic respirations.

CLINICAL ANATOMY

The chest wall of the child is highly elastic, and fractures of the ribs are, therefore, rare. In adults, the ribs may be fractured by direct or indirect violence (Fig. 12.6). In indirect violence, like crush injury, the rib fractures at its weakest point located at the angle. The upper two ribs which are protected by the clavicle, and the lower two ribs which are free to swing are least commonly injured.

Diaphragm descends during inspiration to increase the vertical diameter of thoracic cage.

Hiccups: These occur due to spasmodic involuntary contractions of the diaphragm accompanied by closed glottis. These usually occur due to gastric irritation. Hiccups may also be due to phrenic nerve irritation, uraemia or hysteria.
**INTRODUCTION**

Thorax

Section 2

the thorax from the neck. The membrane is triangular in shape. Its apex is attached to the tip of the transverse process of the seventh cervical vertebra and the base to the inner border of the first rib and its cartilage.

Morphologically, Sibson’s fascia is regarded as the flattened tendon of the scalenus minimus (pleuralis) muscle. It is thus formed by scalenus minimus and endothoracic fascia. Functionally, it provides rigidity to the thoracic inlet, so that the root of the neck is not puffed up and down during respiration. The inferior surface of the membrane is fused to the cervical pleura, beneath which lies the apex of the lung. Its superior surface is related to the subclavian vessels and other structures at the root of the neck (Figs 12.10 and 12.11a and b).

**SUPERIOR APERTURE/INLET OF THORAX**

The narrow upper end of the thorax, which is continuous with the neck, is called the inlet of the thorax (Fig. 12.9). It is kidney-shaped. Its transverse diameter is 10–12.5 cm. The anteroposterior diameter is about 5 cm.

**Boundaries**

*Anteriorly:* Upper border of the manubrium sterni.

*Posteriorly:* Superior surface of the body of the first thoracic vertebra.

*On each side:* First rib with its cartilage.

The plane of the inlet is directed downwards and forwards with an obliquity of about 45°. The anterior part of the inlet lies 3.7 cm below the posterior part, so that the upper border of the manubrium sterni lies at the level of the upper border of the third thoracic vertebra.

**Partition at the Inlet of Thorax**

The partition is in two halves—right and left, with a cleft in between. Each half is covered by a fascia, known as Sibson’s fascia or suprapleural membrane. It partly separates

**Competency achievement:** The student should be able to:

AN 21.3 Describe and demonstrate the boundaries of thoracic inlet, cavity and outlet.

1. The plane of the inlet of the thorax

2. The partition at the inlet of thorax

3. The boundaries of the thoracic inlet, cavity and outlet

Fig. 12.9: The plane of the inlet of the thorax

- Left common carotid artery and the left subclavian artery on the left side.
- Right and left brachiocephalic veins.

**Smaller Vessels**
1. Right and left internal thoracic arteries
2. Right and left superior intercostal arteries
3. Right and left first posterior intercostal veins
4. Inferior thyroid veins

**Nerves**
1. Right and left phrenic nerves
2. Right and left vagus nerves
3. Right and left sympathetic trunks
4. Right and left first thoracic nerves as they ascend across the first rib to join the brachial plexus.

**Muscles**
Sternohyoid, sternothyroid and longus colli
INTRODUCTION

Thorax Section

CLINICAL ANATOMY

• A cervical rib is a rib attached to vertebra C7. It occurs in about 0.5% of subjects (Fig. 12.13). Such a rib may exert traction on the lower trunk of the brachial plexus which arches over a cervical rib. Such a person complains of paraesthesia or abnormal sensations along the ulnar border of the forearm, and wasting of the small muscles of the hand supplied by segment T1 (Fig. 12.14). Vascular changes may also occur.

• In coarctation or narrowing of the aorta, the posterior intercostal arteries get enlarged greatly to provide a collateral circulation. Pressure of the enlarged arteries produces characteristic notching on the ribs (Fig. 12.15) especially in their posterior parts.

• Thoracic inlet syndrome: Two structures arch over the first rib—the subclavian artery and first thoracic nerve. These structures may be pulled or pressed by a cervical rib or by variations in the insertion of the scalenus anterior. The symptoms may, therefore, be vascular, neural, or both.

Fig. 12.13: Cervical rib on both sides

Fig. 12.14: Wasting of small muscles of hand

Fig. 12.15: Tortuous intercostal artery receives blood from anterior intercostal artery; transfers it to descending aorta beyond coarctation. Tortuous intercostal artery produces notches in the rib

INFERIOR APERTURE/OUTLET OF THORAX

The inferior aperture is the broad end of the thorax which surrounds the upper part of the abdominal cavity, but is separated from it by the diaphragm (Greek across fence).

Boundaries

Anteriorly: Infrasternal angle between the two costal margins.

Posteriorly: Inferior surface of the body of the twelfth thoracic vertebra.

On each side: Costal margin formed by the cartilages of seventh to twelfth ribs.

Diaphragm at the Outlet of Thorax

The outlet is closed by a large musculotendinous partition, called the diaphragm—the thoracoabdominal diaphragm—which separates the thorax from the abdomen.
Structures Passing through the Diaphragm

There are three large and several small openings in the diaphragm which allow passage to structures from thorax to abdomen or vice versa (Fig. 12.16).

Large openings: These are vena caval opening in the central tendon, oesophageal opening in the right crus of diaphragm and aortic opening behind the median arcuate ligament.

The structures passing through large openings are put in Table 12.1.

Small openings: Superior epigastric artery passes in space of Larrey present between slip of xiphoid process and 7th costal cartilaginous slip of the diaphragm. When foramen is enlarged it is known as foramen of Morgagni.

Musculophrenic artery perforates diaphragm at the level of 9th costal cartilage.

Lower 5 intercostal vessels and nerves pass between costal origins of diaphragm and transversus abdominis.

Subcostal vessels and nerves pass behind lateral arcuate ligament. Sympathetic trunk passes behind medial arcuate ligament. Greater and lesser splanchnic nerves pierce each crus. Left phrenic nerve pierces left cupola.

FACTS TO REMEMBER

- Thoracic cavity houses a single heart with pericardium, two lungs with pleurae, blood vessels, nerves and lymphatics.
- Rib may be present in relation to cervical seven and lumbar one vertebrae. The cervical rib may give symptoms.
- Ribs are weak at their angles and are vulnerable to injury at that area.
- Apex beat lies below and medial to the normally placed left nipple.
- 2nd costal cartilage at the manubriosternal angle is extremely important landmark. The 2nd intercostal space lies below this cartilage and is used for counting the intercostal spaces for the position of heart, lungs and liver.
- 1–7 ribs with costal cartilages reach the sternum, costal cartilages of 8–10 ribs form the costal margin, while 11th and 12th ribs do not reach the front at all.

CLINICOANATOMICAL PROBLEM

A young adult suffering from chronic anaemia was asked to get sternal puncture done to find out the reason for anaemia.

- What is sternal puncture/bone marrow biopsy?
- Classify bones according to shape.

**Ans:** The sternum is single median line bone in the anterior part of the thoracic cage. It is a flat bone. Its upper part, manubrium is wider and comprises two plates of compact bone with intervening cancellous bone. During sternal puncture, a thick needle is pierced through the skin, fascia and anterior plate of compact bone till it reaches the bone marrow in the cancellous bone. About 0.3 cc of bone marrow is aspirated and slides are prepared immediately to be stained and studied to find out, if the defect is in maturation of RBC or WBC.

Bones are classified as long bone, e.g. humerus; short bone, e.g. tarsal bones; flat bone, e.g. sternum; irregular bone, e.g. vertebra; sesamoid bone, e.g. patella; pneumatic bone, e.g. maxilla.

FURTHER READING

1. Three large openings in the diaphragm are at levels of which of the following thoracic vertebrae?
   a. T8, T9, T10
   b. T7, T8, T9
   c. T8, T10, T12
   d. T9, T10 T12

2. All the following structures course through the inlet of thorax in the median plane, except:
   a. Trachea
   b. Oesophagus
   c. Thymus
   d. Left recurrent laryngeal nerve

3. Suprapleural membrane is attached to:
   a. Anterior aspect of clavicle
   b. Upper border of scapula
   c. Inner margin of 1st rib and its cartilage
   d. Transverse process of 6th cervical vertebra

**Viva Voce**
- What is the importance of sternal angle?
- Name the types of ribs.
- Name the structures passing through the inlet of thorax.
- What symptoms can occur due to fracture of cervical rib?
- Where is the apex beat normally palpable?
- Name the main openings in the diaphragm.
- What structures pass through the aortic opening?
INTRODUCTION
The thorax is an osseocartilaginous cavity or cage for various viscera, providing them due support and protection. This cage is not static, but dynamic, as it moves at its various joints, increasing or decreasing the various diameters of the cavity for an extremely important process of respiration, which is life for all of us.

Competency achievement: The student should be able to:
AN 21.1 Identify and describe the salient features of sternum, typical rib, 1st rib and typical thoracic vertebra.

RIBS OR COSTAE
1 There are 12 ribs on each side forming the greater part of the thoracic skeleton.
   The number may be increased by development of a cervical or a lumbar rib; or the number may be reduced to 11 by the absence of the twelfth rib.
2 The ribs are bony arches arranged one below the other (Fig. 13.1). The gaps between the ribs are called intercostal spaces (see Fig. 12.1).
   The spaces are deeper in front than behind, and deeper between the upper than between the lower ribs.
3 The ribs are placed obliquely, the upper ribs being less oblique than the lower. The obliquity reaches its maximum at the ninth rib, and thereafter it gradually decreases to the twelfth rib.
4 The length of the ribs increases from the first to the seventh ribs, and then gradually decreases from the eighth to twelfth ribs.
5 The breadth of the ribs decreases from above downwards. In the upper 10 ribs, the anterior ends are broader than the posterior ends.

Classification
a. According to articulations with sternum the ribs are true and false: The first 7 ribs which are connected through their cartilages to the sternum are called true ribs, or vertebrosternal ribs. The remaining five are false ribs. Out of these, the cartilages of the eighth, ninth and tenth ribs are joined to the next higher cartilage and are known as vertebrochondral ribs. The anterior ends of the eleventh and twelfth ribs are free and are called floating ribs or vertebral ribs.
b. According to morphological features the ribs are atypical and typical: The first two and last three ribs have special features, and are atypical ribs. The third to ninth ribs are typical ribs.

Typical Ribs

Side Determination
1 The anterior end bears a concave depression. The posterior end bears a head, a neck and a tubercle.
The shaft is convex outwards and there is a costal groove situated along the lower part of its inner surface, so that the lower border is thin and the upper border is rounded.

**Features**

Each rib has two ends—anterior and posterior. Its shaft comprises upper and lower borders and outer and inner surfaces.

The anterior sternal end is oval and concave for articulation with its costal cartilage.

The posterior or vertebral end is made up of the following parts.

1. The head has two facets that are separated by a crest. The lower larger facet articulates with the body of the numerically corresponding vertebra while the upper smaller facet articulates with the next higher vertebra (Figs 13.2 and 13.24).
2. The neck lies in front of the transverse process of its own vertebra, and has two surfaces—anterio and posterior; and two borders—superior and inferior. The anterior surface of the neck is smooth. The posterior surface is rough. The superior border or crest of the neck is thin. The inferior border is rounded.
3. The tubercle is placed on the outer surface of the rib at the junction of the neck and shaft. Its medial part is articular and forms the costotransverse joint with the transverse process of the corresponding vertebra. The lateral part is non-articular (Fig. 13.1).

The shaft is flattened so it has two surfaces—outer and inner; and two borders—upper and lower. The shaft is curved with its convexity outwards (Fig. 13.3). It is bent at the angle which is situated about 5 cm lateral to the tubercle. It is also twisted at the angle.

1. The outer surface: The angle is marked by an oblique line on the outer surface, directed downwards and laterally.
2. The inner surface is smooth and covered by the pleura. This surface is marked by a ridge which is continuous behind with the lower border of the neck. The costal groove lies between this ridge and the inferior border. The costal groove contains the posterior intercostal vessels and intercostal nerve (Fig. 13.4).
3. The upper border is thick and has outer and inner lips.

**Attachments and Relations of a Typical Rib**

1. Anteriorly, the head provides attachment to the radiate ligament (Fig. 13.5) and is related to the sympathetic chain and to the costal pleura.
2. The crest of the head provides attachment to the intra-articular ligament of the costovertebral joint.
3. Attachments to the neck:
   a. The anterior surface is covered by costal pleura.
   b. The inferior costotransverse ligament is attached to the rough posterior surface (Fig. 13.5).
   c. The two laminae of the superior costotransverse ligament are attached to the crest of the neck (Fig. 13.6).
4. The lateral non-articular part of the tubercle gives attachment to the lateral costotransverse ligament (Fig. 13.5).
Attachments on the shaft:

a. The thoracolumbar fascia and the lateral fibres of the sacrospinalis muscle are attached to the angle. Medial to the angle, the levator costae and the sacrospinalis (longissimus) are attached (Fig. 13.8). About 5 cm from the anterior end, there is an indistinct oblique line, known as the anterior angle, which separates the origins of the external oblique from serratus anterior in case of fifth to eighth ribs. The anterior angle also separates the origin of external oblique from that of latissimus dorsi in case of ninth and tenth ribs (Fig. 13.8b).

b. The internal intercostal muscle arises from the floor of the costal groove. The intercostalis intimus arises from the middle two-fourths of the ridge above the groove (Fig. 13.4). The subcostalis is attached to the inner surfaces of the lower ribs.

c. The external intercostal muscle is attached on the outer lip of the upper border, while the internal intercostal and intercostalis intimi are attached on the inner lip of the upper border (Fig. 13.4).

OSSIFICATION OF A TYPICAL RIB

A typical rib ossifies in cartilage from:

a. One primary centre (for the shaft) which appears, near the angle, at about the eighth week of intrauterine life.

b. Three secondary centres, one for the head and two for the tubercle, which appear at puberty and unite with the rest of the bone after 20 years.

Competency achievement: The student should be able to:

AN 21.2 Identify and describe the features of 2nd, 11th and 12th ribs, 1st, 11th and 12th thoracic vertebrae.

First Rib

Identification

1. It is the shortest, broadest and most curved rib.
2. The shaft is not twisted. There is no costal groove.
3. It is flattened from above downwards so that it has superior and inferior surfaces; and outer and inner borders.

Side Determination

1. The anterior end is larger, thicker and pitted. The posterior end is small and rounded.
2. The outer border is convex with no costal groove.
3. The upper surface of the shaft is crossed obliquely by two shallow grooves separated by a ridge. The ridge is enlarged at the inner border of the rib to form the scalene tubercle (Fig. 13.7a).

When the rib is placed on a horizontal plane, i.e. with the superior surface facing upwards, both the ends of the rib touch the surface.
Features of First Rib

1. The *anterior end* is larger and thicker than that in the other ribs. It is continuous with the first costal cartilage.
2. The *posterior end* comprises the following:
   a. The *head* is small and rounded. It articulates with the body of the first thoracic vertebra.
   b. The *neck* is rounded directed laterally, upwards and backwards.
   c. The *tubercle* is large. It coincides with the angle of the rib. It articulates with the transverse process of the first thoracic vertebra to form the *costotransverse joint*.
3. The *shaft (body)* has two surfaces—upper and lower; and two borders—outer and inner.
   a. The *upper surface* is marked by two shallow grooves, separated near the inner border by the scalene tubercle.
   b. The *lower surface* is smooth and has no costal groove.
   c. The *outer border* is convex, thick behind and thin in front.
   d. The *inner border* is concave.

Attachments and Relations

1. Anteriorly, the neck is related from medial to lateral side to:
   a. Sympathetic *chain*
   b. Posterior intercostal vein
   c. Superior intercostal artery
   d. Ventral ramus of the first thoracic nerve (Fig. 13.7a).
      (Mnemonic—*chain* pulling a VAN)
2. Superiorly, the neck is related to:
   a. The deep cervical vessels
   b. The eighth cervical nerve
3. The anterior groove on the superior surface of the shaft lodges the subclavian vein, and the posterior groove lodges the subclavian artery and the lower trunk of the brachial plexus.
4. The structures attached to the upper surface of the shaft are:
   a. The origin of the *subclavius* muscle at the anterior end.
   b. The attachment of the *costoclavicular ligament* at the anterior end behind the subclavius.
   c. The insertion of the *scalenus anterior* on the scalene tubercle.
   d. The insertion of the *scalenus medius* on the elongated rough area behind the groove for the subclavian artery.
5. The lower surface of the shaft is covered by costal pleura and is related near its outer border to the small first intercostal nerve which is very small.
6. The outer border gives origin to:
   a. The *external intercostal muscle*, and
   b. The upper part of the *first digitation of the serratus anterior*, just behind the groove for the subclavian artery. The thick portion of the outer border is covered by the scalenus posterior.
7. The inner border gives attachment to the *suprapleural membrane*.
8. The tubercle gives attachment to the *lateral costotransverse ligament*.

OSSIFICATION

The first rib ossifies from one primary centre for the shaft at the 8th week of intrauterine life. For the shaft there are only two secondary centres, one for the head and the other for the tubercle. These secondary centres appear at puberty and unite with the rest of the bone after 20 years.

Second Rib

Features

The features of the second rib are:

1. The length is twice that of the first rib.
2. The shaft is sharply curved, like that of the first rib.
3. The non-articular part of the tubercle is small.
4. The angle is slight and is situated close to the tubercle.
5. The shaft has no twist. The outer surface is convex and faces more upwards than outwards. Near its middle, it is marked by a large rough tubercle (Fig. 13.7b). This tubercle is a unique feature of the second rib. The inner surface of the shaft is smooth and concave. It faces more downwards than inwards. There is a short costal groove on the posterior part of this surface.

Fig. 13.7b: Superior surface of 2nd rib
The posterior part of the upper border has distinct outer and inner lips. The part of the outer lip just in front of the angle is rough.

**Attachments**
1. The rough tubercle on the outer surface gives origin to 1½ digitations of the serratus anterior muscle.
2. The rough part of the upper border receives the insertion of the scalenus posterior.

**Tenth Rib**
The tenth rib closely resembles a typical rib, but is:
1. Shorter.
2. Has only a single facet on the head, for the body of the tenth thoracic vertebra.

**Eleventh and Twelfth Ribs**
Eleventh and twelfth ribs are short. They have pointed ends. The necks and tubercles are absent. The angle and costal groove are poorly marked in the eleventh rib and are absent in the twelfth rib.

**Attachments and Relations of the Twelfth Rib**
1. The capsular and radiate ligaments are attached to the head of the rib (Fig. 13.6).
2. The following are attached on the inner surface:
   a. The quadratus lumborum is inserted on the lower part of the medial half to two-thirds of this surface (Fig. 13.8a).
   b. The fascia covering the quadratus lumborum is also attached to this part of the rib.
   c. The internal intercostal muscle is inserted near the upper border.
   d. The costodiaphragmatic recess of the pleura is related to the medial three-fourths of the costal surface.
   e. The diaphragm takes origin from the anterior end of this surface.
3. The following are attached to the outer surface.
   a. *Attachments on the medial half*
      i. Costotransverse ligament (Fig. 13.8b).
      ii. Lumbocostal ligament
      iii. Lowest levator costae
      iv. Iliocostalis and longissimus parts of sacrospinalis.
   b. *Attachments on the lateral half*
      i. Insertion of serratus posterior inferior
      ii. Origin of latissimus dorsi
      iii. Origin of external oblique muscle of abdomen.
4. The intercostal muscles are attached to the upper border.
5. The structures attached to the lower border are:
   a. Middle layer of thoracolumbar fascia.
   b. Lateral arcuate ligament, at the lateral border of the quadratus lumborum.
   c. Lumbocostal ligament near the head, extending to the transverse process of first lumbar vertebra.

**Ossification**
The eleventh and twelfth ribs ossify from one primary centre for the shaft and one secondary centre for the head.

**Costal Cartilages**
The costal cartilages represent the unossified anterior parts of the ribs. They are made up of hyaline cartilage. They contribute materially to the elasticity of the thoracic wall.

The medial ends of the costal cartilages of the first seven ribs are attached directly to the sternum. The eighth, ninth and tenth cartilages articulate with one another and form the costal margin. The cartilages of the eleventh and twelfth ribs are small. Their ends are free and lie in the muscles of the abdominal wall.

**Figs 13.8a and b:** The right twelfth rib: (a) Inner surface, and (b) outer surface
The direction of the costal cartilages is variable. As the first costal cartilage approaches the sternum, it descends a little. The second cartilage is horizontal. The third ascends slightly. The remaining costal cartilages are angular. They continue the downward course of the rib for some distance, and then turn upwards to reach either the sternum or the next higher costal cartilage (see Fig. 12.1).

Each cartilage has two surfaces—anterior and posterior; two borders—superior and inferior; and two ends—lateral and medial.

**Attachments**

**Anterior Surface**

1. Anterior surface of the first costal cartilage articulates with the clavicle and takes part in forming the sternoclavicular joint. It gives attachment to:
   a. The sternoclavicular articular disc (see Chapter 10).
   b. The joint capsule of sternoclavicular joint
   c. The costoclavicular ligament
   d. The subclavius muscle (Fig. 13.7)
2. The second to sixth costal cartilages give origin to the pectoralis major (Fig. 13.9).
3. The remaining cartilages are covered by and give partial attachment to some of the flat muscles of the anterior abdominal wall. The internal oblique muscle is attached to the, eighth, ninth and tenth cartilages; and the rectus abdominis to the fifth, sixth and seventh cartilages.

**Posterior Surface**

1. The first cartilage gives origin to the sternothyroid muscle.
2. The second to sixth cartilages receive the insertion of the sternocostalis (Fig. 13.12).
3. The seventh to twelfth cartilages give attachment to the transversus abdominis and to the diaphragm.

**Superior and Inferior Borders**

1. The borders give attachment to the internal intercostal muscles and the external intercostal membranes of the spaces concerned (see Fig. 14.1).
2. The seventh to tenth cartilages articulate with one another at the points of their maximum convexity, to form synovial joints.

**Lateral End**

The lateral end of each cartilage forms a primary cartilaginous joint with the rib concerned.

**Medial End**

1. The first cartilage forms a primary cartilaginous joint with the manubrium.
2. The second to seventh cartilages form synovial joints with the sternum.
3. The eighth and ninth cartilages are connected to the next higher cartilage by synovial joints.
4. The tenth cartilage is united to ninth cartilage by fibrous tissue.
5. The ends of the eleventh and twelfth cartilages are pointed and free.

**CLINICAL ANATOMY**

- Weakest area of rib is the region of its angle. This is the commonest site of fracture.
- Cervical rib occurs in 0.5% of persons. It may articulate with first rib or may have a free end. It may cause pressure on lower trunk of brachial plexus, resulting in paraesthesia along the medial border of forearm and wasting of intrinsic muscles of hand (see Fig. 12.14). It may also cause pressure on the subclavian artery.
- In rickets, there is inadequate mineralisation of bone matrix at the growth plates due to increased bone resorption. Due to deposition of unmineralised matrix, there is widening of the wrist and rachitic rosary, i.e. prominent costochondral junctions in thoracic cage.

**STERNUM**

The sternum is a flat bone, forming the anterior median part of the thoracic skeleton. In shape, it resembles a short sword. The upper part, corresponding to the
handle, is called the manubrium. The middle part, resembling the blade is called the body. The lowest tapering part forming the point of the sword is the xiphoid process or xiphisternum.

The sternum is about 17 cm long. It is longer in males than in females (Figs 13.9 to 13.11).

**Manubrium**

The manubrium is quadrilateral in shape. It is the thickest and strongest part of the sternum. It has two surfaces—anterior and posterior; and four borders—superior, inferior, and two lateral.

The anterior surface is convex from side-to-side and concave from above downwards (Fig. 13.10).

The posterior surface is concave and forms the anterior boundary of the superior mediastinum.

The superior border is thick, rounded and concave. It is marked by the suprasternal notch or jugular notch or interclavicular notch in the median part, and by the clavicular notch on each side. The clavicular notch articulates with the medial end of the clavicle to form the sternoclavicular joint (Fig. 13.11).

The inferior border forms a secondary cartilaginous joint with the body of the sternum. The manubrium makes a slight angle with the body, convex forwards, called the sternal angle of Louis. Events at the sternal angle:

i. Formation of cardiac plexus
   ii. Upper limit of base of heart
   iii. Arch of aorta starts here as continuation of ascending aorta.
   iv. Arch of aorta ends here to continue as descending thoracic aorta.
   v. Trachea divides into 2 branches.

Each lateral border forms a primary cartilaginous joint with the first costal cartilage, and present a demifacet for synovial articulation with the upper part of the second costal cartilage.

**Attachments**

1. The anterior surface gives origin on either side to:
   a. The pectoralis major.
   b. The sternal head of the sternocleidomastoid (Fig. 13.9).

2. The posterior surface gives origin to:
   a. The sternothyroid in upper part (Fig. 13.12).
   b. The sternothyroid in lower part.
   c. The lower half of this surface is related to the arch of the aorta. The upper half is related to the left brachiocephalic vein, the brachiocephalic artery, the left common carotid artery and the left subclavian artery. The lateral portions of the surface are related to the corresponding lung and pleura.

3. The suprasternal notch gives attachment to the lower fibres of the interclavicular ligament, and to the two subdivisions of the investing layer of cervical fascia.

4. The margins of each clavicular notch give attachment to the capsule of the corresponding sternoclavicular joint (see Chapter 10).
Body of the Sternum

The body is longer, narrower and thinner than the manubrium. It is widest close to its lower end opposite the articulation with the fifth costal cartilage. It has two surfaces—anterior and posterior; two lateral borders; and two ends—upper and lower.

1. The anterior surface is nearly flat and directed forwards and slightly upwards. It is marked by three ill-defined transverse ridges, indicating the lines of fusion of the four small segments called sternabrae.

2. The posterior surface is slightly concave and is marked by less distinct transverse lines.

3. The lateral borders form synovial joints with the lower part of the second costal cartilage, the third to sixth costal cartilages, and the upper half of the seventh costal cartilage (Fig. 13.11).

4. The upper end forms a secondary cartilaginous joint with the manubrium at the sternal angle.

5. The lower end is narrow and forms a primary cartilaginous joint with the xiphisternum.

Attachments

1. The anterior surface gives origin on either side to the pectoralis major muscle (Fig. 13.9).

2. The lower part of the posterior surface gives origin on either side to the sternocostalis muscle.

3. On the right side of the median plane, the posterior surface is related to the anterior border of the right lung and pleura. On the left side, the upper two pieces of the body are related to the left lung and pleura, and the lower two pieces to the pericardium (Fig. 13.12).

4. Between the facets for articulation with the costal cartilages, the lateral borders provide attachment to the external intercostal membranes and to the internal intercostal muscles (see Fig. 14.1).

Xiphoid Process

The xiphoid process is the smallest part of the sternum. It is at first cartilaginous, but in the adult it becomes ossified near its upper end. It varies greatly in shape and may be bifid or perforated. It lies in the floor of the epigastric fossa (Fig. 13.10).

Attachments

1. The anterior surface provides insertion to the medial fibres of the rectus abdominis, and to the aponeuroses of the external and internal oblique muscles of the abdomen.

2. The posterior surface gives origin to the diaphragm. It is related to the anterior surface of the liver.

3. The lateral borders of the xiphoid process give attachment to the aponeuroses of the internal oblique and transversus abdominis muscles.

4. The upper end forms a primary cartilaginous joint with the body of the sternum.

5. The lower end affords attachment to the linea alba.
Thorax

Section 2

Inelastic costal cartilages. Indirect violence may lead to fracture of sternum.

- Non-fusion of the sternal plates causes ectopia cordis, where the heart lies uncovered on the surface. Partial fusion of the plates may lead to the formation of sternal foramina, bifid xiphoid process, etc. (Fig. 13.9).

**VERTEBRAL COLUMN**

**Vertebral Column as a Whole**

The vertebral column is also called the spine, the spinal column, or back bone. It is the central axis of the body. It supports the body weight and transmits it to the ground through the lower limbs.

The vertebral column is made up of 33 vertebrae: Seven cervical, twelve thoracic, five lumbar, five sacral and four coccygeal. In the thoracic, lumbar and sacral regions, the number of vertebrae corresponds to the number of spinal nerves, each nerve lying below the corresponding vertebra. In the cervical region, there are eight nerves, the upper seven lying above the corresponding vertebrae and the eighth below the seventh vertebra. In the coccygeal region, there is only one coccygeal nerve.

Sometimes the vertebrae are also grouped according to their mobility. The movable or true vertebrae include the seven cervical, twelve thoracic and five lumbar vertebrae, making a total of 24. Twelve thoracic vertebrae have ribs attached to them. The fixed vertebrae include those of the sacrum and coccyx.

The length of the spine is about 70 cm in males and about 60 cm in females. The intervertebral discs contribute one-fifth of the length of the vertebral column.

As a result of variations in the width of the vertebrae, the vertebral column can be said to be made up of four pyramids (Fig. 13.16a). This arrangement has a functional bearing. The narrowing of the vertebral column at the level of the disc between fourth thoracic and fifth thoracic vertebrae is partly compensated by the transmission of weight to the lower thoracic region through the sternum and ribs.

**Curvatures**

In **Sagittal Plane**

1. **Primary curves** are present at birth due to the shape of the vertebral bodies. The primary curves are thoracic and sacral, both of which are concave forwards.

2. **Secondary curves** are postural and are mainly due to the shape of the intervertebral disc. The secondary or compensatory curves are cervical and lumbar,
both of which are convex forwards. The cervical curve appears during 4 to 5 months after birth when the infant starts supporting its head. The lumbar curve appears during 12 to 18 months when the child assumes the upright posture (Figs 13.16b and c).

In Coronal Plane (Lateral Curve)
There is slight lateral curve in the thoracic region with its concavity towards the left. It is possible due to the greater use of the right upper limb and the pressure of the aorta.

The curvatures add to the elasticity of the spine, and the number of curves gives it a higher resistance to weight than would be afforded by a single curve.

Parts of a Typical Vertebra
A typical vertebra is made up of the following parts:

1. The body lies anteriorly. It is shaped like a short cylinder, being rounded from side-to-side and having flat upper and lower surfaces that are attached to those of adjoining vertebrae by intervertebral discs (Fig. 13.17).
2. The pedicles, right and left, are short rounded bars that project backwards, and somewhat laterally, from the posterior aspect of the body.
3. Each pedicle is continuous, posteromedially, with a vertical plate of bone called the lamina. The laminae of the two sides pass backwards and medially to meet in the midline. The pedicles and laminae together constitute the vertebral or neural arch.
4. Bounded anteriorly by the posterior aspect of the body, on the sides by the pedicles, and behind by the lamina, there is a large vertebral foramen. Each vertebral foramen forms a short segment of the vertebral canal that runs through the whole length of the vertebral column and lodges the spinal cord.
5. Passing backwards and usually downwards from the junction of the two laminae, there is the spine or spinous process (Fig. 13.18).
6. Passing laterally and usually somewhat downwards from the junction of each pedicle and the corresponding lamina, there is a transverse process. The spinous and transverse processes serve as levers for muscles acting on the vertebral column.

From a morphological point of view, the transverse processes are made up of two elements—the transverse element and the costal element. In the thoracic region, the two elements remain separate, and the costal elements form the ribs. In the rest of the vertebral column, the derivatives of costal element are different from those derived from transverse element. This is shown in Table 13.1.
7. Projecting upwards from the junction of the pedicle and the lamina, there is on either side, a superior articular process; and projecting downwards there is an inferior articular process (Fig. 13.19). Each process

Fig. 13.18: Typical thoracic vertebra (5th)—lateral view

Fig. 13.19: Typical thoracic vertebra—posterior aspect

Fig. 13.20: Costal elements in various vertebrae

bears a smooth articular facet: The superior facet of one vertebra articulates with the inferior facet of the vertebra above it.

8 The pedicle is much narrower in vertical diameter than the body and is attached nearer its upper border. As a result, there is a large inferior vertebral notch below the pedicle. Above the pedicle, there is a much shallower superior vertebral notch. The superior and inferior notches of adjoining vertebrae join to form the intervertebral foramina which give passage to the dorsal and ventral rami of the spinal nerves emerging from the spinal cord.

Thoracic Vertebrae

Identification

The thoracic vertebrae are identified by the presence of costal facets on the sides of the vertebral bodies. The costal facets may be two or only one on each side (Fig. 13.18).

There are 12 thoracic vertebrae, out of which the second to eighth are typical, and the remaining five (first, ninth, tenth, eleventh and twelfth) are atypical.
**Typical Thoracic Vertebrae**

1. The body is heart-shaped with roughly the same measurements from side-to-side and antero-posteriorly. On each side, it bears two costal demifacets. The *superior costal demifacet* is larger and placed on the upper border of the body near the pedicle. It articulates with the head of the numerically corresponding rib. The *inferior costal demifacet* is smaller and placed on the lower border in front of the inferior vertebral notch. It articulates with the next lower rib (Fig. 13.18).

2. The *vertebral foramen* is comparatively small and circular.

3. The *vertebral arch* shows:
   a. The *pedicles* are directed straight backwards. The superior vertebral notch is shallow, while the inferior vertebral notch is deep and conspicuous.
   b. The *laminae* overlap each other from above.
   c. The *superior articular processes* project upwards from the junction of the pedicles and laminae. The articular facets are flat and are directed backwards. This direction permits rotatory movements of the spine.
   d. The *inferior articular processes* are fused to the laminae. Their articular facets are directed forwards.
   e. The *transverse processes* are large, and are directed laterally and backwards from the junction of the pedicles and laminae. The anterior surface of each process bears a facet near its tip, for articulation with the tubercle of the corresponding rib. In the upper six vertebrae, the costal facets on the transverse processes are concave, and face forwards and laterally. In lower four, the facets are flat and face upwards, laterally and slightly forwards (Fig. 13.24). In the last two vertebrae, the articular facets are absent (see costotransverse joints below).
   f. The *spine* is long, and is directed downwards and backwards. The fifth to ninth spines are the longest, more vertical and overlap each other. The upper and lower spines are less oblique in direction.

**Attachments**

1. The upper and lower borders of the body give attachment, in front and behind respectively to the *anterior and posterior longitudinal ligaments* (Fig. 13.5).

2. The upper borders and lower parts of the anterior surfaces of the laminae provide attachment to the *ligamenta flava*.

3. The transverse process gives attachment to:
   a. The *lateral costotransverse ligament* at the tip.
   b. The *superior costotransverse ligament* along the lower border.
   c. The *inferior costotransverse ligament* along the anterior surface.
   d. The *intertransverse ligaments* and muscles to upper and lower borders.
   e. The *levator costae* on the posterior surface.

4. The spines give attachment to the *supraspinous and interspinous ligaments*. They also give attachment to several muscles including the *trapezius*, the *rhomboids*, the *latissimus dorsi*, the *serratus posterior superior* and the *serratus posterior inferior*, and many deep muscles of the back.

**First Thoracic Vertebra**

1. The body of this vertebra resembles that of a cervical vertebra. It is broad and not heart-shaped. Its upper surface is lipped laterally and bevelled anteriorly. The superior costal facet on the body is complete (Fig. 13.21). It articulates with the head of the first rib. The inferior costal facet is a ‘demifacet’ for the second rib.

2. The spine is thick, long and nearly horizontal.
3 The superior vertebral notches are well marked, as in cervical vertebrae.
4 Facet on transverse process is concave on T1–T6 vertebrae.

**Ninth Thoracic Vertebra**
The ninth thoracic vertebra resembles a typical thoracic vertebra except that the body has only the superior costal demifacet. The inferior costal facets are absent (Fig. 13.21). Facet on transverse process is flat on T7–T10 vertebrae.

**Tenth Thoracic Vertebra**
The tenth thoracic vertebra resembles a typical thoracic vertebra except that the body has a single complete superior costal facet on each side, extending onto the root of the pedicle (Fig. 13.21).

**Eleventh Thoracic Vertebra**
1 The body has a single large costal facet on each side, extending onto the upper part of the pedicle (Fig. 13.21).
2 The transverse process is small, and has no articular facet.
   Sometimes it is difficult to differentiate between tenth and eleventh thoracic vertebrae.

**Twelfth Thoracic Vertebra**
1 The shapes of the body, pedicles, transverse processes and spine are similar to those of a lumbar vertebra. However, the body bears a single costal facet on each side, which lies more on the lower part of the pedicle than on the body.
2 The transverse process is small and has no facet, but has superior, inferior and lateral tubercles (Fig. 13.21).
3 The inferior articular facets are lumbar in type. These are everted and are directed laterally, but the superior articular facets are thoracic in type.

---

**OSSIFICATION**
The ossifications of typical vertebra and a thoracic vertebra are similar. It ossifies in cartilage from three primary and five secondary centres.

The three primary centres—one for the centrum and one for each half of the neural arch, appear during eighth to ninth weeks of fetal life.

At birth, the vertebra consists of three parts, the centrum and two halves of the neural arch. The two halves of the neural arch fuse posteriorly during the first year of life. The neural arch is joined with the centrum by the neurocentral synchondrosis. Bony fusion occurs here during the third to sixth years of life.

---

**CLINICAL ANATOMY**

- Failure of fusion of the two halves of the neural arch results in ‘spina bifida’. Sometimes the body ossifies from two primary centres, and if one centre fails to develop, one half, right or left of the body is missing. This results in a hemivertebra and lateral bend in the vertebral column or scoliosis.
- In young adults, the discs are very strong. However, after the second decade of life, degenerative changes set in resulting in weakness of the annulus fibrosus. When such a disc is subjected to strain, the annulus fibrosus may rupture leading to prolapse of the nucleus pulposus. This is commonly referred to as disc prolapse. It may occur even after a minor strain. In addition to prolapse of the nucleus pulposus, internal derangements of the disc may also take place.
- Disc prolapse is usually posterolateral. The prolapsed nucleus pulposus presses upon adjacent nerve roots and gives rise to pain that radiates along the distribution of the nerve. Such pain along the course of the sciatic nerve is called sciatica. Motor effects, with loss of power and reflexes, may follow. Disc prolapse occurs most frequently in the lower lumbar region (Fig. 13.23). It is also common in the lower cervical region from fifth to seventh cervical vertebrae.
Fig. 13.24: A section through the costotransverse joints from the third to the ninth inclusive. Contrast the concave facets on the upper with the flattened facets on the lower transverse processes of its own vertebra.

The articular facets on the tubercles of the upper six ribs are convex, and permit rotation of the neck of the rib for pump-handle movements (Fig. 13.24). Rotation of rib-neck backwards causes elevation of second to sixth ribs with moving forwards and upwards of the sternum. This increases the anteroposterior diameter of the thorax (Fig. 13.25).

The articular surfaces of the seventh to tenth ribs are flat, permitting up and down gliding movements or bucket-handle movements of the lower ribs. When the neck of seventh to tenth ribs moves upwards, backwards and medially, the result is increase in infrasternal angle. This causes increase in transverse diameter of thorax (Fig. 13.26).

For explanation of the terms ‘pump-handle’ and ‘bucket-handle’ movements, see ‘Respiratory Movements’.

**JOINTS OF THORAX**

**Manubriosternal Joint**

Manubriosternal joint is a secondary cartilaginous joint. It permits slight movements of the body of the sternum on the manubrium during respiration.

**Costovertebral Joints**

The head of a typical rib articulates with its own vertebra, and also with the body of the next higher vertebra, to form two plane synovial cavities separated by an intra-articular ligament (Fig. 13.6). This ligament is attached to the ridge on the head of the rib and to the intervertebral disc.

Other ligaments of the joint include a capsular ligament and a triradiate ligament. The upper ligament is attached to vertebra above. The lower ligament is attached to vertebra below. The middle band of the triradiate ligament forms the hypochondral bow (Fig. 13.5), uniting the joints of the two sides.

**Costotransverse Joints**

The tubercle of a typical rib articulates with the facet on anterior surface of transverse process of the corresponding vertebra to form a synovial joint.

The capsular ligament is strengthened by three costotransverse ligaments. The superior costotransverse ligament has two laminae which extend from the crest on the neck of the rib to the transverse process of the vertebra above. The inferior costotransverse ligament passes from the posterior surface of the neck to the transverse process of its own vertebra. The lateral costotransverse ligament connects the lateral non-articular part of the tubercle to the tip of the transverse process of its own vertebra.
BONES AND JOINTS OF THORAX

233

Section 2

Costochondral Joints
Each rib is continuous anteriorly with its cartilage, to form a primary cartilaginous joint. No movements are permitted at these joints.

Chondrosternal Joints
The first chondrosternal joint is a primary cartilaginous joint, it does not permit any movement. This helps in the stability of the shoulder girdle and of the upper limb.

The second to seventh costal cartilages articulate with the sternum by synovial joints. Each joint has a single cavity except in the second joint where the cavity is divided in two parts. The joints are held together by the capsular and radiate ligaments.

Interchondral Joints
The fifth to ninth costal cartilages articulate with one another by synovial joints. The tenth cartilage is united to the ninth by fibrous tissue.

The movements taking place at the various joints described above are considered under ‘Respiratory Movements’.

Intervertebral Joints

Adjoining vertebrae (Th 5 and Th 6) are connected to each other at three joints. There is a median joint between the vertebral bodies, and two joints—one on the right side and one on the left side—between the articular processes.

The joints between the articular processes are plane synovial joints.

The joint between the vertebral bodies is a symphysis (secondary cartilaginous joint). The surfaces of the vertebral bodies are lined by thin layers of hyaline cartilage. Between these layers of hyaline cartilage, there is a thick plate of fibrocartilage which is called the intervertebral disc.

Intervertebral Discs
These are fibrocartilaginous discs which intervene between the bodies of adjacent vertebrae, and bind them together. Their shape corresponds to that of the vertebral bodies between which they are placed. The thickness of the disc varies in different regions of the vertebral column, and in different parts of the same disc. In the cervical and lumbar regions, the discs are thicker in front than behind, while in the thoracic region they are of uniform thickness. The discs are thinnest in the upper thoracic region, and thickest in the lumbar region.

The discs contribute about one-fifth of the length of the vertebral column. The contribution is greater in the cervical and lumbar regions than in the thoracic region.

Each disc is made up of the following two parts.

1. The nucleus pulposus is the central part of the disc. It is soft and gelatinous at birth. It is kept under tension and acts as a hydraulic shock absorber. With advancing age, the elasticity of the disc is much reduced (Figs 13.27a and c).

2. The annulus fibrosus forms the peripheral part of the disc. It is made up of a narrower outer zone of collagenous fibres and a wider inner zone of fibrocartilage. The fibres form laminae that are arranged in the form of incomplete rings. The rings are connected by strong fibrous bands. The outer collagenous fibres blend
Functions
1. The intervertebral discs give shape to the vertebral column.
2. They act as a remarkable series of shock absorbers or buffers.
3. Because of their elasticity, they allow slight movement of vertebral bodies on each other, more so in the cervical and lumbar regions. When the slight movements at individual discs are added together, they become considerable.

Ligaments Connecting Adjacent Vertebrae
Apart from the intervertebral discs and the capsules around the joints between the articular processes, adjacent vertebrae are connected by several ligaments which are as follows.
1. The anterior longitudinal ligament passes from the anterior surface of the body of one vertebra to another. Its upper end reaches the basilar part of the occipital bone (Fig. 13.5).
2. The posterior longitudinal ligament is present on the posterior surface of the vertebral bodies within the vertebral canal. Its upper end reaches the body of the axis vertebra (C2) beyond which it is continuous with the membra tectoria (Fig. 13.5).
3. The intertransverse ligaments connect adjacent transverse processes.
4. The interspinous ligaments connect adjacent spines.
5. The supraspinous ligaments connect the tips of the spines of vertebrae from the seventh cervical to the sacrum. In the cervical region, they are replaced by the ligamentum nuchae.
6. The ligamenta flava (singular = ligamentum flavum) connect the laminae of adjacent vertebrae. They are made up mainly of elastic tissue.

Movements of the Vertebral Column
Movements between adjacent vertebrae occur simultaneously at all the joints connecting them. Movement between any two vertebrae is slight. However, when the movements between several vertebrae are added together the total range of movement becomes considerable. The movements are those of flexion, extension, lateral flexion and a certain amount of rotation. The range of movement differs in different parts of the vertebral column. This is influenced by the thickness and flexibility of the intervertebral discs and by the orientation of the articular facets.
Flexion and extension occur freely in the cervical and lumbar regions, but not in the thoracic region. Rotation is free in the thoracic region, and restricted in the lumbar and cervical regions.

Competency achievement: The student should be able to:
AN 21.9 Describe and demonstrate mechanics and types of respiration.

RESPIRATORY MOVEMENTS

Introduction
The lungs expand during inspiration and retract during expiration. These movements are governed by the following two factors.
1. Alterations in the capacity of the thorax are brought about by movements of the thoracic wall. Increase in volume of the thoracic cavity creates a negative intrathoracic pressure which sucks air into the lungs. Movements of the thoracic wall occur chiefly at the costovertebral and manubriosternal joints.
2. Elastic recoil of the pulmonary alveoli and of the thoracic wall expels air from the lungs during expiration.

Principles of Movements
1. Each rib may be regarded as a lever, the fulcrum of which lies just lateral to the tubercle. Because of the disproportion in the length of the two arms of the lever, the slight movements at the vertebral end of the rib are greatly magnified at the anterior end (Fig. 13.28).
BONES AND JOINTS OF THORAX

2 The anterior end of the rib is lower than the posterior end. Therefore, during elevation of the rib, the anterior end also moves forwards. This occurs mostly in the vertebrosternal ribs. Along with the up and down movements of the second to sixth ribs, the body of the sternum also moves up and down called pump-handle movements (Fig. 13.29). In this way, the anteroposterior diameter of the thorax is increased.

3 The middle of the shaft of the rib lies at a lower level than the plane passing through the two ends. Therefore, during elevation of the rib, the shaft also moves outwards. This causes increase in the transverse diameter of the thorax. Such movements occur in the vertebrochondral ribs, and are called bucket-handle movements.

4 The thorax resembles a cone, tapering upwards. As a result, each rib is longer than the next higher rib. On elevation, the larger lower rib comes to occupy the position of the smaller upper rib which pushes sternum forwards. This also increases the transverse diameter of the thorax (Fig. 13.30).

5 Vertical diameter is increased by the ‘piston movements’ of the thoracoabdominal diaphragm (Fig. 13.31).
Summary of the Factors Producing Increase in Diameters of the Thorax

The anteroposterior diameter is increased:
1. Mainly by the pump-handle movements of the sternum brought about by elevation of the vertebrosternal second to sixth ribs.
2. Partly by elevation of the seventh to tenth vertebrochondral ribs.

The transverse diameter is increased:
1. Mainly by the bucket-handle movements of the seventh to tenth vertebrochondral ribs.
2. Partly by elevation of the second to sixth vertebrosternal ribs.

The vertical diameter is increased by descent of the diaphragm as it contracts. This is called piston mechanism. During inspiration, the diaphragm contracts and it comes down by 2 cm. It is aided by relaxation of muscles of anterior abdominal wall. During expiration, abdominal muscles contract and diaphragm is pushed upwards. It facilitates in inspiration of at least 400 ml of air during each contraction.

In females, respiration is thoracoabdominal and in males it is abdominothoracic type.

Respiratory Muscles
For inspiration—diaphragm, external intercostal muscle and interchondral part of internal intercostal of contralateral side.
Deep inspiration—erector spinae, scalene muscles, pectoral muscles.
For expiration—passive process.
Forced expiration—muscles of anterior abdominal wall.

Respiratory Movements during Different Types of Breathing

Inspiration
1. Quiet inspiration
   a. The anteroposterior diameter of the thorax is increased by elevation of the second to sixth ribs. The first rib remains fixed.
   b. The transverse diameter is increased by elevation of the seventh to tenth ribs.
   c. The vertical diameter is increased by descent of the diaphragm.
2. Deep inspiration
   a. Movements during quiet inspiration are increased.
   b. The first rib is elevated directly by the scaleni, and indirectly by the sternocleidomastoid.
   c. The concavity of the thoracic spine is reduced by the erector spinae.
3. Forced inspiration
   a. All the movements described are exaggerated.

Expiration
1. Quiet expiration: The air is expelled mainly by the elastic recoil of the chest wall and pulmonary alveoli, and partly by the tone of the abdominal muscles.
2. Deep and forced expiration: Deep and forced expiration is brought about by strong contraction of the abdominal muscles and of the latissimus dorsi.

CLINICAL ANATOMY

• In dyspnoea or difficulty in breathing, the patients are most comfortable on sitting up, leaning forwards and fixing the arms. In the sitting posture, the position of diaphragm is the lowest allowing maximum ventilation. Fixation of the arms fixes the scapulae, so that the serratus anterior and pectoralis minor may act on the ribs.

• The height of the diaphragm in the thorax is variable according to the position of the body and tone of the abdominal muscles. It is highest on lying supine, so the patient is extremely uncomfortable, as he/she needs to exert immensely for inspiration. The diaphragm is lowest while sitting. The patient is quite comfortable as the effort required for inspiration is the least.

The diaphragm is midway in position while standing, but the patient is too ill or exhausted to stand. So dyspnoeic patients feel comfortable while sitting (Figs 13.32a to c).

• Most prominent role in respiration is played by diaphragm.

• Respiration occurs in two phases:
  Inspiration—active phase of 1 second
  Expiration—passive phase of 3 second.

• In young children (up to 2 years of age), the thoracic cavity is almost circular in cross-section so the scope for anteroposterior or side-to-side expansion is limited. The type of respiration in children is abdominal.

• In women of advanced stage of pregnancy, descent of diaphragm is limited, so the type of respiration in them is mainly thoracic.
Mnemonics

**Structures in costal groove: VAN from above downwards**
- Posterior intercostal vein
- Posterior intercostal artery
- Intercostal nerve

**Structures on neck of 1st rib: sympathetic trunk and VAN from medial to lateral side**
- Posterior intercostal vein
- Superior intercostal artery
- 1st thoracic nerve

**Vertebrae: Recognising a Thoracic from Lumbar**
- Presence of costal facets on the sides of the body and transverse process
- Shape of the vertebral body
  - Thoracic is heart-shaped body (since your heart is in your thorax).
  - Lumbar is kidney-/bean-shaped body (since kidneys are in lumbar area)
- Spine is long and oblique

**FACTS TO REMEMBER**
- Sternum forms joints with its own parts:
  - One manubriosternal joint—secondary cartilaginous.
- Three joints between sternabrae—primary cartilaginous.
- One joint between sternum and xiphoid process—primary cartilaginous.
- Sternum forms two joints with clavicles of the two sides—saddle type of synovial joint.
- It articulates with 1st–7th costal cartilages on each side forming a total of 14 joints—all plane synovial joints except 1st chondrosternal which is synchondrosis.
- A typical thoracic vertebra forms following joints:
  - Body of one vertebrae with body of vertebra above and body of vertebra below—secondary cartilaginous joint (2 joints).
  - Lower larger part of head of corresponding rib for the demifacet along the upper border of the body on each side (2 cavities, 1 joint).
  - Upper smaller part of head of a lower rib for the demifacet along the lower border of the body on each side (2 cavities, 1 joint).
  - Superior articular processes on each side with the inferior articular processes of the vertebra above (2 joints).
  - Inferior articular processes on each side with the superior articular processes of the vertebra below (2 joints).
  - Transverse process of the vertebra with the articular part of the tubercle of the rib on each side (2 joints).
  - Body of the vertebra with the pedicle of the vertebra on each side—primary cartilaginous joints (2 joints).

Thus there are 12 joints which a typical thoracic vertebra makes.
- 2 secondary cartilaginous joints
- 2 primary cartilaginous joints
- 8 plane joints of synovial variety

- The ribs are arched bones. Joints formed by a typical rib are:
  - Posterior end or head of a typical rib articulates with two adjacent vertebrae, corresponding one and one above it and the intervening intervertebral disc.
  - The articular part of the tubercle articulates with transverse process of corresponding vertebra.
  - The anterior part of the shaft of rib continues as the costal cartilage. It is primary cartilaginous joint.
  - A costal cartilage forms plane synovial joint with the side of sternum.

- Respiratory movements produced by movements of thoracoabdominal diaphragm are called ‘abdominal respiration’.
- Respiratory movements produced by movements of intercostal muscles are called ‘thoracic respiration’.

Figs 13.32a to c: Position of diaphragm: (a) Sitting, (b) standing, and (c) lying down
1. Transverse diameter of thoracic cage increases by:
   a. Pump-handle movement of ribs
   b. Bucket-handle movement of ribs
   c. Caliper movement of ribs
   d. Contraction of diaphragm

2. Anteroposterior diameter of thorax increases by:
   a. Pump-handle movement of ribs
   b. Bucket-handle movement of ribs
   c. Contraction of diaphragm
   d. Relaxation of diaphragm

3. Which one of the following joints is a primary cartilaginous joint?
   a. Costovertebral
   b. Costotransverse
   c. First costochondral
   d. Manubriosternal

4. Which of the following ribs articulates with one vertebra only?
   a. First
   b. Second
   c. Third
   d. Fourth

5. When do the secondary curvatures appear in the vertebral column?

6. Name the joints formed by typical thoracic vertebra.

7. Give an account of the various respiratory movements. Name the muscles responsible for inspiratory and expiratory movements.

During ‘Pranayama’, deep regulated and smooth breathing occurs.

- Which diameters increase during deep breathing?

**Ans:** The anteroposterior diameter increases by ‘pump-handle movement’ of the sternum.

The transverse diameter increases by the ‘bucket-handle movement’ of the 7–10 ribs.

The vertical diameter increases by ‘piston movement’ of the thoracoabdominal diaphragm.

During inspiration, the vertical diameter increases by 3–5 cm and during expiration, the vertical diameter decreases.

**FURTHER READING**

8. The lower larger facet on the head of a typical rib articulates with the demifacet on:
   a. Inferior part of corresponding vertebrae
   b. Superior part of corresponding vertebrae
   c. Inferior part of vertebra above the corresponding vertebrae
   d. Superior part of vertebra below the corresponding vertebrae

**Answers**
1. b  
2. a  
3. c  
4. a  
5. c  
6. c  
7. c  
8. b

**Viva Voce**
- Name the vertebrae with which head of 4th rib articulates.
- What structures lie at the neck of 1st rib?
- Costodiaphragmatic recesses lie in relation to which rib. What is its clinical importance?
- What type of joint is manubriosternal joint?
- Name the blood vessels related to manubrium sterni.
- What is sternal puncture? Where is it done and why?
- Which are the primary and secondary curvatures of the vertebral column?
- What are pump-handle and bucket-handle movements?
INTRODUCTION
The thorax is covered by muscles of pectoral region of upper limb. In addition, the intercostal muscles and membranes fill up the gaps between adjacent ribs and cartilages. These muscles provide integrity to the thoracic wall. A right and left pair of thoracic nerves fulfil the exact definition of the dermatome.

The posterior intercostal vein, posterior intercostal artery and intercostal nerve (VAN) lie from above downwards in the costal groove of the ribs.

Sympathetic part of autonomic nervous system starts from the lateral horns of thoracic 1 to thoracic 12 segments of the spinal cord. It continues up to lumbar 2 segment.

Coverings of the Thoracic Wall
The thoracic wall is covered from outside to inside by the following structures—skin, superficial fascia, deep fascia, and extrinsic muscles. The extrinsic muscles covering the thorax are as follows.

Muscles of the Upper Limb
1. Pectoralis major
2. Trapezius
3. Serratus anterior
4. Pectoralis minor
5. Latissimus dorsi
6. Levator scapulae
7. Rhomboid major
8. Rhomboid minor
9. Serratus posterior superior
10. Serratus posterior inferior

Muscles of the Abdomen
1. Rectus abdominis
2. External oblique

Muscles of the Back
Erector spinae (sacrospinalis).

In addition to the muscles listed above, a number of other muscles of the abdomen and of the head and neck are attached to the margins of the two apertures of the thorax.

THORACIC WALL PROPER
Features
The thoracic cage forms the skeletal framework of the wall of the thorax. The gaps between the ribs are called intercostal spaces. They are filled by the intercostal muscles and contain the intercostal nerves, vessels and lymphatics. There are nine intercostal spaces anteriorly and eleven intercostal spaces posteriorly.

Competency achievement: The student should be able to:
AN 21.4 Describe and demonstrate extent, attachments, direction of fibres, nerve supply and actions of intercostal muscles.¹

INTERCOSTAL MUSCLES
These are:
1. The external intercostal muscle
2. The internal intercostal muscle
   Each comprises intercartilaginous in front and interosseous in posterolateral part.
3. The transversus thoracis muscle which is divisible into three parts, namely the subcostalis, the intercostalis intimi (innermost intercostal) and the sternocostalis. The attachments of these muscles are given in Table 14.1.

Extent
The external intercostal muscle extends from the tubercle of the rib posteriorly to the costochondral junction anteriorly. Between the costochondral junction and the
sternum, it is replaced by the external or anterior intercostal membrane. The posterior end of the muscle is continuous with the posterior fibres of the superior costotransverse ligament (Figs 14.1a and b).

The internal intercostal muscle extends from the lateral border of the sternum to the angle of the rib. Beyond the angle, it becomes continuous with the internal or posterior intercostal membrane, which is continuous with the anterior fibres of the superior costotransverse ligament.

The subcostalis is confined to the posterior part of the lower intercostal spaces only.

The intercostalis intimi is confined to the middle two-fourths of all the intercostal spaces (Fig. 14.4).

The sternocostalis is present in relation to the anterior parts of the upper intercostal spaces (Fig. 14.4).

**Direction of Fibres**

In the anterior part of the intercostal space:

1. The fibres of the external intercostal muscle run downwards, forwards and medially in front.
2. The fibres of the internal intercostal run downwards, backwards and laterally, i.e. at right angle to those of the external intercostal.
3. The fibres of the transversus thoracis run in the same direction as those of the internal intercostal.

**Nerve Supply**

All intercostal muscles are supplied by the intercostal nerves of the spaces in which they lie.

**Actions of the Intercostal Muscles**

1. The main action of the intercostal muscles is to prevent intercostal spaces being drawn in during inspiration and bulging outwards during expiration.
2. The external intercostals, interchondral portions of the internal intercostals, and the levator costae may elevate the ribs during inspiration.
3. The internal intercostals except for the interchondral portions and the transversus thoracis may depress the ribs or cartilages during expiration.

Competency achievement: The student should be able to:

AN 21.5 Describe and demonstrate origin, course, relations and branches of a typical intercostal nerve.

AN 21.7 Mention the origin, course, relations and branches of:

1. Atypical intercostal nerve.
2. Superior intercostal artery, subcostal artery.

INTERCOSTAL NERVES

The intercostal nerves are the ventral primary rami of thoracic one to thoracic eleven (Fig. 14.3) spinal nerves after the dorsal primary ramus has been given off. The anterior primary ramus of the twelfth thoracic nerve forms the subcostal nerve. In addition to supplying the intercostal spaces, the upper two intercostal nerves also supply the upper limb. The lower five intercostal nerves, seventh to eleventh thoracic nerves, also supply abdominal wall. These are, therefore, said to be thoraco-abdominal nerves. The remaining nerves, third to sixth, supply only the thoracic wall; they are called typical intercostal nerves.

The subcostal nerve is distributed to the abdominal wall and to the skin of the buttock.

Course

Intercostal nerve runs in the costal groove and ends near the sternum.

Relations

1. Each nerve passes below the neck of the rib of the same number and enters the costal groove.
2. In the costal groove, the nerve lies below the posterior intercostal vessels. The relationship of structures in the costal groove from above downwards is posterior intercostal vein, posterior intercostal artery and intercostal nerve (VAN) (Fig. 14.2).

In the posterior part of the costal groove, the nerve lies between the pleura, with the endothoracic fascia and the internal intercostal membrane.

In the greater part of the space, the nerve lies between the intercostalis intimi and the internal intercostal muscle (Fig. 14.4).

3. Near the sternum, the nerve crosses in front of the internal thoracic vessels and the sternocostalis muscle. It then pierces the internal intercostal muscle, the external intercostal membrane and the pectoralis major muscle to terminate as the anterior cutaneous nerve of the thorax.

Branches

Muscular Branches

1. Numerous muscular branches supply the intercostal muscles, the transversus thoracis and the serratus posterior superior.
2. A collateral branch arises near the angle of the rib and runs in the lower part of the space in the same neurovascular plane. It supplies muscles of the space.

Sensory Branches

1. The main branch and the collateral branch also supply parietal pleura, periosteum of the ribs. The lower nerves in addition supply the parietal peritoneum.
2. The lateral cutaneous branch arises near the angle of the rib and accompanies the main trunk up to the lateral thoracic wall where it pierces the intercostal muscles and other muscles of the body wall along the midaxillary line. It is distributed to the skin after dividing into anterior and posterior branches.
3. The anterior cutaneous branch emerges on the side of the sternum to supply the overlying skin after dividing into medial and lateral branches.

Communicating Branches

1. Each nerve is connected to a thoracic sympathetic ganglion by a distally placed white and a proximally placed grey ramus communicans (Fig. 14.3).
2. The lateral cutaneous branch of the second intercostal nerve is known as the intercostobrachial nerve. It supplies the skin of the floor of the axilla and of the upper part of the medial side of the arm (see Fig. 7.1).

DISSECTION

Detach the serratus anterior and the pectoralis major muscles from the upper ribs. Note the external intercostal muscle in the second and third intercostal spaces. Its fibres run anteroinferiorly. Follow it forwards to the external intercostal membrane which replaces it between the costal cartilages (Figs 14.1a and b and 14.2).
Cut the external intercostal membrane and muscle along the lower border of two spaces. Reflect them upwards to expose the internal intercostal muscle. The direction of its fibres is posteroinferior, at right angle to that of external oblique.

Follow the lateral cutaneous branch of one intercostal nerve to its trunk deep to internal intercostal muscle.

Trace the nerve and accompanying vessels round the thoracic wall. Note their collateral branches lying along the upper margin of the rib below. Trace the muscular branches of the trunk of intercostal nerve and its collateral branch. Trace the anterior cutaneous nerve as well (Fig. 14.3).
Identify the deepest muscle in the intercostal space, the innermost intercostal muscle (Table 14.1). This muscle is deficient in the anterior and posterior ends of the intercostal spaces, where the neurovascular bundle rests directly on the parietal pleura.

Expose the internal thoracic artery 1 cm from the lateral margin of sternum by carefully removing the intercostal muscles and membranes from the upper three intercostal spaces (Fig. 14.11a).

Trace the artery through the upper six intercostal spaces and identify its two terminal branches (see Fig. 21.7). Trace its venae comitantes upwards till third costal cartilage where these join to form internal thoracic vein, which drains into the brachiocephalic vein.

Follow the course and branches of both anterior and posterior intercostal arteries including the course and tributaries of azygos vein (refer to BDC App).

**CLINICAL ANATOMY**

- Irritation of the intercostal nerves causes severe pain which is referred to the front of the chest or abdomen, i.e., at the peripheral termination of the nerve. This is known as root pain or girdle pain.
- Herpes virus may cause infection of intercostal nerves. If herpes infection is in 2nd thoracic nerve, there is referred pain via intercostobrachial nerve to the upper medial side of arm.
- Internal thoracic artery is mobilised and its distal cut end is joined to the coronary artery distal to its narrowed segment.
- Pus from the vertebral column tends to track around the thorax along the course of the neurovascular bundle, and may point at any of the three sites of exit of the branches of a thoracic nerve; one dorsal primary ramus and two cutaneous branches (Fig. 14.5).
- In superior vena caval obstruction before the entry of vena azygos, the vena azygos is the main channel which transmits the blood from the upper half of the body to distal part of superior

**Flowchart 14.1: Superior vena cava blockage before entry of vena azygos**

  - Vena azygos
- Superior vena cava
  - Right atrium

**Fig. 14.5:** Possible paths of cold abscess (due to TB of vertebra) along the branches of spinal nerve
TYPICAL INTERCOSTAL SPACES

Typical intercostal spaces are the spaces whose intercostal nerves and vessels are confined to thoracic wall only.

**Boundaries**

*Superior:* Upper border of the costal groove of the rib above.

*Inferior:* Blunt upper border of the rib below.

*Anterior:* Lateral border of sternum.

*Posterior:* Body of thoracic vertebra.

**Contents**

1. All intercostal muscles
2. Two anterior intercostal arteries and veins
3. Posterior intercostal artery and vein with its collateral branch and tributary
4. Intercostal nerve and its collateral branch (Fig. 14.2)

**INTERCOSTAL ARTERIES**

Each intercostal space contains one posterior intercostal artery with its collateral branch and two anterior intercostal arteries. The greater part of the space is supplied by the posterior intercostal artery (Fig. 14.7).

**Posterior Intercostal Arteries**

These are 11 in number on each side, one in each space.

1. The first and second posterior intercostal arteries arise from the superior intercostal artery which is a branch of costocervical trunk of the subclavian artery.

2. The third to eleventh arteries arise from the descending thoracic aorta (Fig. 14.8). The right-sided arteries are longer than those of the left side as aorta is to the left of median plane.

**Course and Relations**

*In front of the vertebrae:* The right posterior intercostal arteries are longer than the left, and pass behind the oesophagus, the thoracic duct, the azygos vein and the sympathetic chain (Fig. 14.9).

The left posterior intercostal arteries pass behind the hemiazygos vein and the sympathetic chain.

*In the intercostal space:* The artery is accompanied by the intercostal vein and nerve, the relationship from above downwards being vein–artery–nerve (VAN).
The neurovascular bundle runs forwards in the costal groove, first between the pleura and the internal intercostal membrane and then between the internal intercostal and intercostalis intimi muscles (Fig. 14.4).

**Termination**

Each posterior intercostal artery ends at the level of the costochondral junction by anastomosing with the upper anterior intercostal artery of the space (Fig. 14.7).

**Branches**

1. A dorsal branch supplies the muscles and skin of the back, and gives off a spinal branch to the spinal cord and vertebrae (Fig. 14.7).
2. A collateral branch arises near the angle of the rib, descends to the upper border of the lower rib, and
ends by anastomosing with the lower anterior intercostal artery of the space.

3 Muscular arteries are given off to the intercostal muscles, the pectoral muscles and the serratus anterior.

4 A lateral cutaneous branch accompanies the nerve of the same name.

5 Mammary branches arise from the second, third and fourth arteries and supply the mammary gland.

6 The right bronchial artery arises from the right third posterior intercostal artery.

**Anterior Intercostal Arteries**

There are nine intercostal spaces anteriorly as only ten ribs reach front of body. There are two anterior intercostal arteries in each space. In the upper six spaces, they arise from the internal thoracic artery (see Fig. 21.7). In seventh to ninth spaces, the arteries are branches of musculophrenic artery. The two anterior intercostal arteries end at the costochondral junction by anastomosing with the respective posterior intercostal arteries and with the collateral branches of the posterior intercostal arteries.

**INTERCOSTAL VEINS**

There are two anterior intercostal veins in each of the upper nine spaces. They accompany the corresponding arteries. In the upper three spaces, the veins end in the internal thoracic vein. In 4-6 spaces, the veins end in venae comitantes accompanying internal thoracic artery. In the succeeding spaces, they end in the venae comitantes accompanying musculophrenic artery.

There is one posterior intercostal vein and one collateral vein in each intercostal space. Each vein accompanies the corresponding artery and lies superior to the artery. The tributaries of these veins correspond to the branches of the arteries. They include veins from the vertebral canal, the vertebral venous plexus, and the muscles and skin of the back. Vein accompanying the collateral branch of the artery drains into the posterior intercostal vein.

The mode of termination of the posterior intercostal veins is different on the right and left sides as given in Table 14.2, and shown in Fig. 14.10.

**Fig. 14.10:** The veins on the posterior thoracic wall. Note the drainage of the posterior intercostal veins
The azygos and hemiazygos veins are described later.

LYMPHATICS OF AN INTERCOSTAL SPACE

Lymphatics from the anterior part of the spaces pass to the anterior intercostal or internal mammary nodes which lie along the internal thoracic artery. Their efferents unite with those of the tracheobronchial and brachiocephalic nodes to form the bronchomediastinal trunk, which joins the right lymphatic trunk on the right side and the thoracic duct on the left side.

Lymphatics from the posterior part of the space pass to the posterior intercostal nodes which lie on the heads and necks of the ribs. Their efferents in the lower four spaces unite to form a trunk which descends and opens into the cisterna chyli. The efferents from the upper spaces drain into left bronchomediastinal lymph trunk on the left side and into right bronchomediastinal lymph trunk on the right side (see Fig. 20.13).

INTERNAL THORACIC ARTERY

Origin

Internal thoracic artery arises from the inferior aspect of the first part of the subclavian artery opposite the thyrocervical trunk. The origin lies 2 cm above the sternal end of the clavicle (Figs 14.11a and b).

Beginning, Course and Termination

Internal thoracic artery arises from lower border of 1st part of subclavian artery. It descends medially and downwards behind sternal end of clavicle, and 1st costal cartilage. Runs vertically downwards 2 cm from lateral border of sternum till 6th intercostal space. The artery terminates in the sixth intercostal space by dividing into the superior epigastric and musculophrenic arteries.

The artery is accompanied by two venae comitantes which unite at the level of the fourth costal cartilage to form the internal thoracic or internal mammary vein. The vein runs upwards along the medial side of the artery to end in the brachiocephalic vein at the inlet of the thorax.

A chain of lymph nodes lies along the artery.

Relations

Above the first costal cartilage, it runs downwards, forwards and medially, behind:
1. The sternal end of the clavicle
2. The internal jugular vein
3. The brachiocephalic vein
4. The first costal cartilage
5. The phrenic nerve. It descends in front of the cervical pleura.

Below the first costal cartilage, the artery runs vertically downwards up to its termination in the 6th intercostal space. Its relations are as follows.

Anteriorly
1. Pectoralis major
2. Upper six costal cartilages
3. External intercostal membranes
4. Internal intercostal muscles
5. The first six intercostal nerves (Fig. 14.4).

Figs 14.11a and b: (a) The origin of the internal thoracic artery from the first part of the subclavian artery, (b) course of internal thoracic artery.
Posteriorly
The endothoracic fascia and pleura up to the second or third costal cartilage. Below this level, the sternocostalis muscle separates the artery from the pleura (Fig. 14.12).

Branches
1 The pericardiophrenic artery arises in the root of the neck and accompanies the phrenic nerve to reach the diaphragm. It supplies the pericardium and the pleura (see Fig. 15.1).
2 The mediastinal arteries are small irregular branches that supply the thymus, in front of the pericardium, and the fat in the mediastinum.
3 Two anterior intercostal arteries are given to each of the upper six intercostal spaces.
4 The perforating branches accompany the anterior cutaneous nerves. In the female, the perforating branches in the second, third and fourth spaces are large and supply the breast.
5 The superior epigastric artery runs downwards behind the seventh costal cartilage and enters the rectus sheath by passing between the sternal and costal slips of the diaphragm (Fig. 14.11b).
6 The musculophrenic artery runs downwards and laterally behind the seventh, eighth, and ninth costal cartilages. It gives two anterior intercostal branches to each of these three spaces. It perforates the diaphragm near the 9th costal cartilage and terminates by anastomosing with other arteries on the undersurface of the diaphragm (Fig. 14.11b).

Note that through its various branches, the internal thoracic artery supplies the anterior thoracic and abdominal walls from the clavicle to the umbilicus.

AZYGOS VEIN
The azygos vein drains the thoracic wall and the upper lumbar region (Figs 14.10 and see 20.6b and c). It forms an important channel connecting the superior and inferior venae cavae. The term ‘azygos’ means unpaired. The vein occupies the upper part of the posterior abdominal wall and the posterior mediastinum. It also connects portal venous system, caval venous system and vertebral venous system.

Formation
The azygos vein is formed by union of the lumbar azygos, right subcostal and right ascending lumbar veins.
1 The lumbar azygos vein may be regarded as the abdominal part of the azygos vein. It lies to the right of the lumbar vertebrae. Its lower end communicates with the inferior vena cava.
2 The right subcostal vein accompanies the corresponding artery.
3 The ascending lumbar vein is formed by vertical anastomoses that connect the lumbar veins. The azygos vein may be formed by union of the right subcostal and ascending lumbar veins (Fig. 14.10).

Course
1 The azygos vein enters the thorax by passing through the aortic opening of the diaphragm (see Fig. 12.16).
2 The azygos vein then ascends up to fourth thoracic vertebra where it arches forwards over the root of the right lung and ends by joining the posterior aspect of the superior vena cava before it pierces the pericardium (see Fig. 15.2).

Relations
Anteriorly: Oesophagus.
Posteriorly:
1 Lower eight thoracic vertebrae
2 Right posterior intercostal arteries

Competency achievement: The student should be able to:
AN 23.3 Describe and demonstrate origin, course, relations, tributaries and termination of superior vena cava, azygos, hemiazygos and accessory hemiazygos veins.
For superior vena cava see chapter 19.
To the right:
1 Right lung and pleura
2 Greater splanchnic nerve

To the left:
1 Thoracic duct and aorta in lower part
2 Oesophagus, trachea and vagus in the upper part

Tributaries
1 Right superior intercostal vein formed by union of the second, third and fourth posterior intercostal veins.
2 Fifth to eleventh right posterior intercostal veins (Fig. 14.10).
3 Hemiazygos vein at the level of lower border of eighth thoracic vertebra.
4 Accessory hemiazygos vein at the level of upper border of eighth thoracic vertebra.
5 Right bronchial vein, near the terminal end of the azygos vein.
6 Several oesophageal, mediastinal, pericardial veins.

HEMIAZYGOS VEIN
Hemiazygos vein is also called the inferior hemiazygos vein. It is the mirror image of the lower part of the azygos vein. The hemiazygos is formed by the union of the left lumbar azygos, left ascending lumbar, and left subcostal veins (Fig. 14.10).

Course
Hemiazygos vein pierces the left crus of the diaphragm, ascends on the left side of the vertebra overlapped by the aorta. At the level of eighth thoracic vertebra, it turns to the right, passes behind the oesophagus and the thoracic duct, and joins the azygos vein (Fig. 14.10).

Tributaries
Ninth to eleventh left posterior intercostal veins and oesophageal veins.

ACCESSORY HEMIAZYGOS VEIN
Accessory hemiazygos vein is also called the superior hemiazygos vein. It is the mirror image of the upper part of the azygos vein.

Course
Accessory hemiazygos vein begins at the medial end of the fourth or fifth intercostal space, and descends on the left side of the vertebral column. At the level of eighth thoracic vertebra, it turns to the right, passes behind the aorta and the thoracic duct, and joins the azygos vein.

Tributaries
1 Fifth to eighth left posterior intercostal veins
2 Sometimes the left bronchial veins.

Competency achievement: The student should be able to:
AN 23.5 Identify and mention the location and extent of thoracic sympathetic chain.
AN 23.6 Describe the splanchnic nerves.

THORACIC SYMPATHETIC TRUNK
Features
The thoracic sympathetic trunk is a ganglionated chain situated one on each side of the thoracic vertebral column. Superiorly, it is continuous with the cervical part of the chain and inferiorly with the lumbar part (Figs 14.13 and 14.14).

Theoretically, the chain bears 12 ganglia corresponding to the 12 thoracic nerves. The first thoracic ganglion is commonly fused with the inferior cervical ganglion to form the cervicothoracic, or stellate ganglion. The remaining thoracic ganglia generally lie at the levels of the corresponding intervertebral discs and the intercostal nerves.

Course and Relations
The chain crosses the neck of the first rib, the heads of the second to tenth ribs, and bodies of the eleventh and twelfth thoracic vertebrae. The whole chain descends in front of the posterior intercostal vessels and the intercostal nerves, and passes deep to the medial arcuate ligament to become continuous with the lumbar part of the sympathetic chain.

Branches
Lateral Branches for the Limbs and Body Wall
Each ganglion is connected with its corresponding spinal nerve by two rami, the white (preganglionic) and grey (postganglionic) rami communicantes. The white ramus is distal to the grey ramus (see Appendix; Fig. A2.3). The grey rami communicantes along with spinal nerves supply structures in the skin and blood vessels of skeletal muscles of the whole body (Fig. 14.14).

Medial Branches for the Viscera
1 Medial branches from the upper 5 ganglia are postganglionic and get distributed to the heart, the great vessels, the lungs and the oesophagus, through the following.
a. Pulmonary branches to the pulmonary plexuses
b. Cardiac branches to the deep cardiac plexus
c. Aortic branches to thoracic aortic plexus

d. Oesophageal branches which join the oesophageal plexus (Fig. 14.13).

2. Medial branches from the lower 7 ganglia are preganglionic and form three splanchnic nerves.
   a. The greater splanchnic nerve is formed by 5 roots from ganglia 5 to 9. It descends obliquely on the vertebral bodies, pierces the crus of the diaphragm, and ends (in the abdomen) mainly in the coeliac ganglion, and partly in the aortico-renal ganglion and the suprarenal gland.
   
   b. The lesser splanchnic nerve is formed by two roots from ganglia 10 and 11. Its course is similar to that of the greater splanchnic nerve. It pierces the crus of the diaphragm, and ends in the coeliac ganglion (Fig. 14.14).
   
   c. The least (lowest) splanchnic nerve (renal nerve) is tiny. It arises by one root from ganglion 12. It pierces the corresponding crus of the diaphragm.

The sympathetic nervous system may be revised from Chapter 7 of BD Chaurasia’s Handbook of General Anatomy, 6th edition.

---

**CLINICAL ANATOMY**

- Cardiac pain is an ischaemic pain caused by incomplete obstruction of a coronary artery.

Axons of pain fibres conveyed by the sensory sympathetic cardiac nerves reach thoracic one to thoracic five segments of spinal cord mostly through the dorsal root ganglia of the left side. Since these dorsal root ganglia also receive sensory impulses from the medial side of arm, forearm and upper part of front of chest, the pain gets referred to these areas as depicted in Fig. 18.26.
Fig. 14.14: Autonomic nervous system and its divisions: Sympathetic and parasympathetic nervous systems
Though the pain is usually referred to the left side, it may even be referred to right arm, jaw, epigastrium or back.

### FACTS TO REMEMBER
- Intercostal spaces are 11 on the back and only 9 in front of chest.
- Intercostal muscles are in 3 layers—external, internal and transversus. These correspond to the muscle layers of anterior abdominal wall.
- Neurovascular bundle lies in the upper part of the intercostal space in between internal and innermost intercostal muscles.
- Posterior intercostal artery and its collateral branch supplies two-thirds of the intercostal space.
- Right posterior intercostal arteries are longer than the left ones.
- Accessory hemiazygos vein drains 5–8 left intercostal spaces and hemiazygos vein drains 9–11 left intercostal spaces. Corresponding veins on right side drain into vena azygos.

### CLINICOANATOMICAL PROBLEM
One student is climbing the stairs at a fast pace as he is late for his examination and the lift got out of order. His heart is beating fast against his chest wall. He has dryness of mouth and sweating of the palm.

- What is the reason for rapid heart beat (tachycardia)?
- What is the effect of sympathetic on the skin?

**Ans:** As he is late for the examination, the sympathetic system gets overactive, increasing the heart rate, and blood pressure.

Sympathetic has three fold effect on the skin, i.e. vasomotor, pilomotor and sudomotor. The sweat secretion is markedly increased, including the pale skin with hair standing erect.

Sympathetic activity decreases the secretion of the glands. Dryness of mouth results from decreased salivary secretion.

### FURTHER READING

1. Describe the course, branches of a typical thoracic spinal nerve. What is its applied anatomy?
2. Describe the internal thoracic artery under following headings: Origin, course, termination and branches.
3. Write short notes on:
   a. Posterior intercostal arteries
   b. Vena azygos
   c. Splanchnic nerves
   d. Cardiac pain referred to medial side of left arm
   e. Structures in the costal groove in order
   f. Name the parts of parietal pleura with their nerve supply.
   g. Name the recesses of the pleura. What is their clinical importance?
Multiple Choice Questions

1. The order of structures in the upper part of intercostal space from above downwards is:
   a. Vein, artery and nerve
   b. Artery, vein and nerve
   c. Vein, nerve and artery
   d. Vein, nerve, artery and vein

2. Parts of transversus thoracis are all, except:
   a. Subcostalis
   b. Intercostalis intimi
   c. Sternocostalis
   d. Serratus posterior superior

3. Which of the following arteries are enlarged in coarctation of aorta?
   a. Subclavian
   b. Internal mammary
   c. Posterior intercostals
   d. Anterior intercostals

4. Which posterior intercostal veins of left side drain into accessory hemiazygos vein?
   a. 1st to 5th
   b. 2nd to 4th
   c. 9th to 11th
   d. 5th to 8th

5. Which one is not a branch of internal thoracic artery?
   a. Superior epigastric
   b. Musculophrenic
   c. Anterior intercostal
   d. Posterior intercostal

6. Thoracolumbar outflow starts from lateral horn of which segments of spinal cord?
   a. T1–L1 segments
   b. T1–T12 segments
   c. T1–L2 segments
   d. T1–L5 segments

7. Following are the effects of sympathetic on skin, except:
   a. Sudomotor
   b. Vasomotor
   c. Pilomotor
   d. Decreased pigmentation

Answers
1. a  2. d  3. c  4. d  5. d  6. c  7. d

Viva Voce

- Name the structures ‘in order’ present in a costal groove.
- Which are the typical intercostal nerves?
- What is the importance of thoracoepigastric vein?
- What does the word ‘azygos’ mean?
- How many spinal nerves have both white and grey rami communicantes?
- How many intercostal spaces are present on anterior and posterior aspects of thoracic cage?
- What is the common site for paracentesis thoracis and why is this procedure carried out?
Thoracic Cavity and Pleurae

Laughter is the best medicine but being seldom used
—Anonymous

THORACIC CAVITY

The spongy lungs occupying a major portion of thoracic cavity are enveloped in a serous cavity—the pleural cavity. There is always slight negative pressure in this cavity. During inspiration, the pressure becomes more negative, and air is drawn into the lungs covered with its visceral and parietal layers of pleura. Visceral layer is inseparable from the lung and is supplied and drained by the same arteries, veins and nerves as lungs. In a similar manner, the parietal pleura follows the walls of the thoracic cavity with cervical, costal, diaphragmatic and mediastinal parts. Pleural cavity limits the expansion of the lungs (Figs 15.1a–c).

DISSECTION

Divide the manubrium sterni transversely immediately inferior to its junction with the first costal cartilage. Cut through the parietal pleura in the first intercostal space on both sides as far back as possible. Cut sternum at the level of xiphisternal joint. Use a bone cutter to cut 2nd to 7th ribs in midaxillary line on each side of thorax. Separate intercostal muscles in 1–6 spaces from underlying pleura.

Lift the inferior part of manubrium and body of sternum with ribs and costal cartilages and reflect it towards abdomen. Identify the pleura extending from the back of sternum onto the mediastinum to the level of lower border of heart. Note the smooth surface of pleura where it lines the thoracic wall and covers the lateral aspects of mediastinum. Trace the surface marking of parietal pleura on the skeleton.

Remove the pleura and the endothoracic fascia from the back of sternum and costal cartilages which is reflected towards abdomen. Identify the transversus thoracis muscle and internal thoracic vessels.

Note the origin of diaphragm from the xiphoid process and divide it. Identify the course and branches of intercostal nerve again. Trace the nerve medially superficial to the internal thoracic vessels.

Pull the lung laterally from the mediastinum and find its root with the pulmonary ligament extending downwards from it. Cut through the structures, i.e. bronchus/bronchi, pulmonary vessels, nerves, comprising its root from above downwards close to the lung. Remove the lung on each side. Be careful not to injure the lung or your hand from the cut ends of the ribs.

Identify the phrenic nerve with accompanying blood vessels anterior to the root of the lung. Make a longitudinal incision through the pleura only parallel to and on each side of the phrenic nerve. Strip the pleura posterior to the nerve backwards to the intercostal spaces. Pull the anterior flap forwards to reveal part of the pericardium with the heart. Identify the following structures seen through the pleura.

Right side
1. Bulge of the heart and pericardium anteroinferior to the root of the lung (Fig. 15.2).
2. A longitudinal ridge formed by right brachiocephalic vein down to first costal cartilage and by superior vena cava up to the bulge of the heart.
3. A smaller longitudinal ridge formed by inferior vena cava formed between the heart and the diaphragm.
4. Phrenic nerve with accompanying vessels forming a vertical ridge on these two venae cavae passing anterior to root of the lung.
5. Vena azygos arching over root of the lung to enter the superior vena cava.
6. Trachea and oesophagus posterior to the phrenic nerve and superior vena cava.
7. Right vagus nerve descending posteroinferiorly across the trachea, behind the root of the lung.
Fig. 15.1: (a) Schematic transverse section of the thorax showing parts of the thoracic cavity, (b) vertical reflections of the pleura, (c) transverse reflections of the pleura

Fig. 15.2: Mediastinum as seen from the right side
8. Bodies of the thoracic vertebrae behind oesophagus with posterior intercostal vessels and azygos vein lying over them.
9. Sympathetic trunk on the heads of the upper ribs and on the sides of the vertebral bodies below this, anterior to the posterior intercostal vessels and intercostal nerves.

**Left side**
1. Bulge of the heart (Fig. 15.3).
2. Root of lung posterolateral to it.
3. Descending aorta between (1) and (2) in front and vertebral column behind.
4. Arch of aorta over the root of the lung.
5. Left common carotid and left subclavian arteries passing superiorly from the arch of aorta.
6. Phrenic and vagus nerves descending between these vessels and the lateral surface of the aortic arch.
7. Sympathetic trunk same as on right side. Identify longitudinally running sympathetic trunk on the posterior part of thoracic cavity. Find delicate greater and lesser splanchnic nerves arising from the trunk on the medial side. Look carefully for grey and white rami communicantes between the intercostal nerve and the ganglia on the sympathetic trunk (see Fig. 14.3).
8. Trace the intercostal vessels above the intercostal nerve. The order being vein, artery and nerve (VAN).

On the right side, identify and follow one of the divisions of trachea to the lung root and the superior and inferior venae cavae till the pericardium.

On the left side of thoracic cavity, dissect the arch of aorta. Identify the superior cervical cardiac branch of the left sympathetic trunk and the inferior cervical cardiac branch of the left vagus on the arch of aorta between the vagus nerve posteriorly and phrenic nerve anteriorly (cardiac nerves) (see Fig. 19.9).

The cavity of the thorax contains the right and left pleural cavities which are completely invaginated and occupied by the lungs. The right and left pleural cavities are separated by a thick median partition called the mediastinum. The heart lies in the mediastinum.

**Competency achievement:** The student should be able to:

*AN 24.1* Mention the blood supply, lymphatic drainage and nerve supply of pleura, extent of pleura and describe the pleural recesses and their applied anatomy.

**PLEURAE**

**Features**
Like the peritoneum, the pleura is a serous membrane which is lined by mesothelium (flattened epithelium). There are two pleural sacs, one on either side of the...
mediastinum. Each pleural sac is invaginated from its medial side by the lung, so that it has an outer layer, the parietal pleura, and an inner layer, the visceral or pulmonary pleura. The two layers are continuous with each other around the hilum of the lung, and enclose between them a potential space, the pleural cavity.

Table 15.1 shows comparison between visceral pleura and parietal pleura.

Pulmonary/Visceral Pleura
The serous layer of pulmonary pleura covers the surfaces and fissures of the lung, except at the hilum and along the attachment of the pulmonary ligament where it is continuous with the parietal pleura. It is firmly adherent to the lung and cannot be separated from it.

Surface Marking of the Lung/Visceral Pleura
The apex of the visceral pleura coincides with the cervical pleura, and is represented by a line convex upwards with a point 1 rising 2.5 cm above the medial one-third of the clavicle (Fig. 15.4).

The anterior border of the right visceral pleura corresponds very closely to the anterior margin or costomediastinal line of the pleura and is obtained by joining:
- A point 2 at the sternoclavicular joint,
- A point 3 in the median plane at the sternal angle,
- A point 4 in the median plane just above the xiphisternal joint.

The anterior border of the left visceral pleura corresponds to the anterior margin of the pleura up to the level of the fourth costal cartilage points 1–IV left side.

Fig. 15.4: Surface projection of the parietal pleura (black); visceral pleura and lung (pink) on the front of thorax
In the lower part, it presents a cardiac notch of variable size. From the level of the fourth costal cartilage, it passes laterally for 3.5 cm from the sternal margin (V), and then curves downwards and medially to reach the sixth costal cartilage 4 cm from the median plane (VI). In the region of the cardiac notch, the pericardium is covered only by a double layer of pleura. The area of the cardiac notch is dull on percussion and is called the area of superficial cardiac dullness (Fig. 15.4).

The lower border of each visceral pleura lies two ribs higher than the parietal pleural reflection. It crosses the sixth rib in the midclavicular line (5), the eighth rib in the midaxillary line (6 and VII), the tenth rib at the lateral border of the erector spinae, and ends 2 cm lateral to the tenth thoracic spine.

**Parietal Pleura**

The parietal pleura is thicker than the pulmonary pleura, and is subdivided into the following four parts.

1. Costal
2. Diaphragmatic
3. Mediastinal
4. Cervical (Figs 15.5a and b)

The costal pleura lines the thoracic wall which comprises ribs and intercostal spaces to which it is loosely attached by a layer of areolar tissue called the endothoracic fascia.

The mediastinal pleura lines the corresponding surface of the mediastinum. It is reflected over the root of the lung and becomes continuous with the pulmonary pleura around the hilum.

The cervical pleura extends into the neck, nearly 5 cm above the first costal cartilage and 2.5 cm above the medial one-third of the clavicle, and covers the apex of the lung (see Fig. 12.10). It is covered by the suprapleural membrane. Cervical pleura is related anteriorly to the subclavian artery and the scalenus anterior; posteriorly to the neck of the first rib and structures lying over it; laterally to the scalenus medius; and medially to the large vessels of the neck (see Fig. 12.10).

Diaphragmatic pleura lines the superior aspect of diaphragm. It covers the base of the lung and gets continuous with mediastinal pleura medially and costal pleura laterally.

**Features of Parietal Pleura**

The cervical pleura is represented by a curved line forming a dome over the medial one-third of the clavicle with a height of about 2.5 cm above the clavicle (Fig. 15.4). Pleura lies in the root of neck on both sides.

The anterior margin, or the costomediastinal line of pleural reflection is as follows: On the right side, it extends from the sternoclavicular joint downwards and medially to the midpoint of the sternal angle. From here, it continues vertically downwards to the midpoint of the xiphisternal joint crosses to right of xiphocostal angle. On the left side, the line follows the same course up to the level of the fourth costal cartilage. It then arches outwards and descends along the sternal margin up to the sixth costal cartilage.

The inferior margin, or the costodiaphragmatic line of pleural reflection passes laterally from the lower limit of its anterior margin, so that it crosses the eighth rib in the midclavicular line, the tenth rib in the midaxillary line, and the twelfth rib at the lateral border of the sacrospinalis muscle. Further it passes horizontally a little below the 12th rib to the lower border of the twelfth thoracic vertebra, 2 cm lateral to the upper border of the twelfth thoracic spine (Fig. 15.7).

Thus the parietal pleurae descend below the costal margin at three places, at the right xiphicostal angle, and at the right and left costovertebral angles, below the twelfth rib behind the upper poles of the kidneys.
The latter fact is of surgical importance in exposure of the kidney. The pleura may be damaged at this site (Fig. 15.7).

The posterior margins of the pleura pass from a point 2 cm lateral to the twelfth thoracic spine to a point 2 cm lateral to the seventh cervical spine. The costal pleura becomes the mediastinal pleura along this line.

**Pulmonary Ligament**

The parietal pleura surrounding the root of the lung extends downwards beyond the root as a fold called the pulmonary ligament. The fold contains a thin layer of loose areolar tissue with a few lymphatics. Actually, it provides a dead space into which the pulmonary veins can expand during increased venous return as in exercise. The lung roots can also descend into it with the descent of the diaphragm (Fig. 15.6).

**Recesses of Pleura**

There are two recesses of parietal pleura, which act as ‘reserve spaces’ for the lung to expand during deep inspiration (Figs 15.7 and 15.8).

- The costomediastinal recess (Fig. 15.4) lies anteriorly, behind the sternum and costal cartilages, between the costal and mediastinal pleurae, particularly in relation to the cardiac notch of the left lung. This recess is filled up by the anterior margin of the lungs even during quiet breathing. It is only obvious in the region of the cardiac notch of the lung.

- The costodiaphragmatic/costovertebral recess lies inferiorly between the costal and diaphragmatic pleurae. Vertically, it measures about 5 cm, and extends from the eighth to tenth ribs along the midaxillary line (Fig. 15.7).

  During inspiration, the lungs expand into these recesses. So these recesses are obvious only in expiration and not in deep inspiration.

**Nerve Supply of the Pleura**

The parietal pleura develops from the somatopleuric layer of the lateral plate mesoderm, and is supplied by the somatic nerves. These are the intercostal and phrenic nerves. The parietal pleura is pain sensitive. The costal and peripheral parts of the diaphragmatic pleurae are supplied by the intercostal nerves, and the mediastinal pleura and central part of the diaphragmatic pleurae are supplied by the phrenic nerves (C4).

The pulmonary pleura develops from the splanchnopleuric layer of the lateral plate mesoderm, and is supplied by autonomic nerves. The sympathetic nerves are derived from second to fifth sympathetic ganglia while parasympathetic nerves are drawn from the vagus nerve. The nerves accompany the bronchial vessels. This part of the pleura is not sensitive to pain.

Sympathetic system dilates the bronchi. The parasympathetic system narrows the bronchial tree and is also secretory to the glands.
Blood Supply and Lymphatic Drainage of Pleura

The parietal pleura is a part and parcel of the thoracic wall. Its blood supply and lymphatic drainage are, therefore, the same as that of the body wall. It is thus supplied by intercostal, internal thoracic and musculophrenic arteries.

The veins drain mostly into the azygos and internal thoracic veins. The lymphatics drain into the intercostal, internal mammary, posterior mediastinal and diaphragmatic nodes.

The pulmonary pleura, like the lung, is supplied by the bronchial arteries while the veins drain into bronchial veins. It is drained by the bronchopulmonary lymph nodes.

CLINICAL ANATOMY

- Aspiration of any fluid from the pleural cavity is called paracentesis thoracis. It is usually done in the eighth intercostal space in the midaxillary line (Fig. 15.9). The needle is passed through the lower part of the space to avoid injury to the principal neurovascular bundle, i.e. vein, artery and nerve (VAN).

- Some clinical conditions associated with the pleura are as follows.
  a. Pleurisy: This is inflammation of the pleura. It may be dry, but often it is accompanied by collection of fluid in the pleural cavity. The condition is called the pleural effusion (Fig. 15.10). Dry pleurisy is more painful because during inspiration both layers come in contact and there is friction.
  b. Pneumothorax: Presence of air in the pleural cavity.
  c. Haemothorax: Presence of blood in the pleural cavity.
  d. Hydropneumothorax: Presence of both fluid and air in the pleural cavity.
  e. Empyema: Presence of pus in pleural cavity.

- Costal and peripheral parts of diaphragmatic pleurae are innervated by intercostal nerves (Fig. 15.11). Hence irritation of these regions cause referred pain along intercostal nerves to thoracic or abdominal wall. Mediastinal and central parts of diaphragmatic pleurae are innervated by phrenic nerve (C4). Hence irritation here causes referred pain on tip of shoulders.

- Pain on right shoulder occurs due to inflammation of gallbladder, while on left shoulder is due to splenic rupture.

- Pleural effusion causes obliteration of costodiaphragmatic recess.

---

Fig. 15.9: Paracentesis thoracis

Fig. 15.10: Pleural effusion

Fig. 15.11: Nerve supply of parietal pleura. Costal pleura and cervical pleura innervated by intercostal nerves, and mediastinal pleura and central part of diaphragmatic pleura innervated by phrenic nerve
• Pleura extends beyond the thoracic cage at following areas:
  - Right xiphicostal angle (Fig. 15.4)
  - Right and left costovertebral angles (Fig. 15.7)
  - Right and left sides of root of neck as cervical dome of pleura (Fig. 15.4).
  
  The pleura may be injured at these sites during surgical procedures. These sites have to be remembered.

• During inspiration, pure air is withdrawn in the lungs. At the same time, deoxygenated blood is received through the pulmonary arteries. Thus an exchange of gases occurs at the level of alveoli. The deoxygenated blood gets oxygenated and sent via pulmonary veins to the left atrium of heart. The impure air containing carbon dioxide gets expelled during expiration.

Mnemonics

**Pleura surface markings**

“All the even ribs, in order: 2, 4, 6, 8, 10, 12 show its route”.

*Rib 2:* Both sides parietal pleura come close

*Rib 4:* The left pleura does a lateral shift to accommodate heart

*Rib 6:* Both diverge laterally

*Rib 8:* Midclavicular line

*Rib 10:* Midaxillary line

*Rib 12:* The back

**FACTS TO REMEMBER**

• Parietal pleura limits the expansion of the lungs.

• Visceral pleura behaves in same way as the lung.

• Parietal pleura has same nerve supply and blood supply as the thoracic wall.

• Pleural cavity normally contains a minimal serous fluid for lubrication during movements of thoracic cage.

• Pleura lies beyond the thoracic cage at 5 places. These are right and left cervical pleurae above the 1st rib and the clavicle; right and left costovertebral angles and only right xiphicostal angle. Pleura is likely to be injured at these places.

• Paracentesis thoracis is done in the lower part of the intercostal space to avoid injury to the main intercostal vessels and nerve.

• Pleural effusion is one of the sign of tuberculosis of the lung.

**CLINICOANATOMICAL PROBLEM**

A child about 10 years of age had been having sore throat, cough and fever. On the third day, he developed severe cough, difficulty in breathing and high temperature, with pain in his right side of chest, right shoulder and around umbilicus.

• What is the probable diagnosis?

• Why does pain radiate to right shoulder and periumbilical region?

**Ans:** The most probable diagnosis is pneumonia of the right lung. The infection from pharynx spreads down to the lungs. Pleura consists of two layers—visceral and parietal; the former is insensitive to pain and the latter is sensitive to pain. The costal part of parietal pleura is supplied by intercostal nerves and the mediastinal and central parts of diaphragmatic pleurae are supplied by phrenic nerve (C4).

In pneumonia, there is always an element of pleural infection. The pain of pleuritis radiates to other areas. Due to infection in mediastinal and central part of diaphragmatic pleura, the pain is referred to tip of the right shoulder as this area is supplied by supraclavicular nerves with the same root value as phrenic nerve (C4).

The costal pleura is supplied by intercostal nerves. These nerves also supply the skin of anterior abdominal wall. So the pain of lower part of costal pleura gets referred to skin of abdomen, in the periumbilical area.

INTRODUCTION
The lungs occupying major portions of the thoracic cavity, leave little space for the heart, which excavates more of the left lung. The two lungs hold the heart tight between them, providing it the protection, it rightly deserves. There are ten bronchopulmonary segments in each lung.

The lungs are a pair of respiratory organs situated in the thoracic cavity. Each lung invaginates the corresponding pleural cavity. The right and left lungs are separated by the mediastinum.

The lungs are spongy in texture. In the young, the lungs are brown or grey in colour. Gradually, they become mottled black because of the deposition of inhaled carbon particles. The right lung weighs about 700 g; it is about 50 to 100 g heavier than the left lung.

DISSECTION
Identify the lungs by the thin anterior border, thick posterior border, conical apex, wider base, medial surface with hilum and costal surface with impressions of the ribs and intercostal spaces. In addition, the right lung is distinguished by the presence of three lobes, whereas left lung comprises two lobes only (refer to BDC App).

On the mediastinal part of the medial surface of right lung identify two bronchi—the eparterial and hyparterial bronchi, with bronchial vessels and posterior pulmonary plexus, the pulmonary artery between the two bronchi on an anterior plane. The upper pulmonary vein is situated still on an anterior plane while the lower pulmonary vein is identified below the bronchi.

The impressions on the right lung in front of root of lung are of superior vena cava, inferior vena cava, and right ventricle. The impressions behind the root of lung are those of vena azygos and oesophagus (Table 16.1).

Hilum of the left lung shows the single bronchus situated posteriorly, with bronchial vessels and posterior pulmonary plexus. The pulmonary artery lies above the bronchus. Anterior to the bronchus is the upper pulmonary vein, while the lower vein lies below the bronchus.

The mediastinal surface of left lung has the impression of left ventricle, ascending aorta. Behind the root of the left lung are the impressions of descending thoracic aorta while oesophagus leaves an impression in the lower part only (Refer to BDC App).

LUNGS
Features
Each lung is conical in shape (Fig. 16.1). It has:
1. An apex at the upper end.
2. A base resting on the diaphragm.
3. Three borders, i.e. anterior, posterior and inferior.
4. Two surfaces, i.e. costal and mediastinal. The medial surface is divided into vertebral and mediastinal parts.

The apex is blunt and lies above the level of the anterior end of the first rib. It reaches nearly 2.5 cm above the medial one-third of the clavicle, just medial to the supraclavicular fossa. It is covered by the cervical pleura, the suprapleural membrane, and is grooved by the subclavian artery on the medial side and anteriorly (see Fig. 12.10).

The base is semilunar and concave. It rests on the diaphragm which separates the right lung from the right lobe of the liver, and the left lung from the left lobe of the liver, the fundus of the stomach, and the spleen (see Fig. 15.8).

The anterior border is very thin (Figs 16.2 and 16.3). It is shorter than the posterior border. On the right side, it is vertical and corresponds to the anterior or costomediastinal line of pleural reflection. The anterior border of the left lung shows a wide cardiac notch below the level of the fourth costal cartilage. The heart and pericardium are not covered by the lung in the region of this notch.
Section 2

LUNGS

Fissures and Lobes of the Lungs

The right lung is divided into three lobes (upper, middle and lower) by two fissures (oblique and horizontal). The left lung is divided into two lobes by the oblique fissure (Fig. 16.1a).

The oblique fissure cuts into the whole thickness of the lung, except at the hilum. It passes obliquely downwards and forwards, crossing the posterior border about 6 cm below the apex and the inferior border about 5 cm from the median plane. Due to the oblique plane of the fissure, the lower lobe is more posterior and the upper and middle lobes more anterior.

In the right lung, the horizontal fissure passes from the anterior border up to the oblique fissure and separates a wedge-shaped middle lobe from the upper lobe. The fissure runs horizontally at the level of the fourth costal cartilage and meets the oblique fissure in the midaxillary line.

The tongue-shaped projection of the left lung below the cardiac notch is called the lingula. It corresponds to the middle lobe of the right lung.

The lungs expand maximally in the inferior direction because movements of the thoracic wall and diaphragm are maximal towards the base of the lung. The presence of the oblique fissure of each lung allows a more uniform expansion of the whole lung.

Surface Marking of the Lung

Surface marking of lung is same as that of visceral pleura described in Chapter 15. The surface marking of oblique and horizontal fissures is mentioned here.

The oblique fissure can be drawn by joining:

a. A point 2 cm lateral to the third thoracic spine.

b. Another point on the fifth rib in the midaxillary line (see Fig. 15.4).

2. On left side: Arch of the aorta.

**Inferior**
Pulmonary ligament.

**Differences between the Right and Left Lungs**
Differences between right and left lungs are given in Table 16.2.

**Arterial Supply**
The bronchial arteries supply nutrition to the bronchial tree and to the pulmonary tissue. These are small arteries that vary in number, size and origin, but usually they are as follows:
1. On the right side, there is one bronchial artery which arises from the third right posterior intercostal artery.

2. On the left side, there are two bronchial arteries, both of which arise from the descending thoracic aorta, the upper opposite fifth thoracic vertebra and the lower just below the left bronchus.

Deoxygenated blood is brought to the lungs by the two pulmonary arteries and oxygenated blood is returned to the heart by the four pulmonary veins.

There are precapillary anastomoses between bronchial and pulmonary arteries. These connections enlarge when any one of them is obstructed in disease.

**Fig. 16.4a:** Roots of the right and left lungs

**Fig. 16.4b:** Gross anatomy of lungs including their roots
Venous Drainage of the Lungs

The venous blood from the first and second divisions of the bronchi is carried by bronchial veins. Usually there are two bronchial veins on each side. The right bronchial veins drain into the azygos vein. The left bronchial veins drain into the hemiazygos vein.

The greater part of the venous blood from the lungs is drained by the pulmonary veins.

Lymphatic Drainage

There are two sets of lymphatics, both of which drain into the bronchopulmonary nodes.

1. Superficial vessels drain the peripheral lung tissue lying beneath the pulmonary pleura. The vessels pass round the borders of the lung and margins of the fissures to reach the hilum.

2. Deep lymphatics drain the bronchial tree, the pulmonary vessels and the connective tissue septa. They run towards the hilum where they drain into the bronchopulmonary nodes (Fig. 16.4a).

The superficial vessels have numerous valves and the deep vessels have only a few valves or no valves at all. Though there is no free anastomosis between the superficial and deep vessels, some connections exist which can open up, so that lymph can flow from the deep to the superficial lymphatics when the deep vessels are obstructed in disease of the lungs or of the lymph nodes.

Nerve Supply

1. Parasympathetic nerves are derived from the vagus. These fibres are:
   a. Motor to the bronchial muscles, and on stimulation cause bronchospasm.
   b. Secretomotor to the mucous glands of the bronchial tree.
   c. Sensory fibres are responsible for the stretch reflex of the lungs, and for the cough reflex.

2. Sympathetic nerves are derived from second to fifth sympathetic ganglia. These are inhibitory to the smooth muscle and glands of the bronchial tree. This is how sympathomimetic drugs, like adrenaline, cause bronchodilatation and relieve symptoms of bronchial asthma.

Both parasympathetic and sympathetic nerves first form anterior and posterior pulmonary plexuses situated in front of and behind the lung roots: From the plexuses, nerves are distributed to the lungs along the blood vessels and bronchi (Fig. 16.4).

Features

The trachea divides at the level of the lower border of the fourth thoracic vertebra into two primary principal bronchi, one for each lung. The right principal bronchus is 2.5 cm long. It is shorter, wider and more in line with the trachea than the left principal bronchus (Fig. 16.5a). Inhaled particles or foreign bodies, therefore, tend to pass more frequently to the right lung, with the result that infections are more common on the right side than on the left.

The left principal bronchus is 5 cm. It is longer, narrower and more oblique than the right bronchus. Right bronchus makes an angle of 25° with tracheal bifurcation, while left bronchus makes an angle of 45° with the trachea.

Each principal bronchus enters the lung through the hilum, and divides into secondary lobar bronchi, one for each lobe of the lungs. Thus there are three lobar bronchi on the right side, and only two on the left side. Each lobar bronchus divides into tertiary or segmental bronchi, one for each bronchopulmonary segment; which are 10 on the right side and 10 on the left side. The segmental bronchi divide repeatedly to form very small branches called terminal bronchioles. Still smaller branches are called respiratory bronchioles (Fig. 16.6).

Each respiratory bronchiole aerates a small part of the lung known as a pulmonary unit. The respiratory bronchiole ends in microscopic passages which are termed:

1. Alveolar ducts (Fig. 16.7)
2. Atria
3. Air saccules
4. Pulmonary alveoli (Latin small cavity). Gaseous exchanges take place in the alveoli.

Dissection

Dissect the principal bronchus into the left lung. Remove the pulmonary tissue and follow the main bronchus till it is seen to divide into two lobar bronchi. Try to dissect till these divide into the segmental bronchi (Fig. 16.5a).

Dissect the principal bronchus into the right lung. Remove the pulmonary tissue and follow the main bronchus till it is seen to divide into three lobar bronchi. Try to dissect till these divide into segmental bronchi.

Competency achievement: The student should be able to:

AN 24.3 Describe a bronchopulmonary segment. 
Bronchopulmonary Segments

The most widely accepted classification of segments is given in Table 16.3. There are 10 segments on the right side and 10 on the left side (Figs 16.5a–c and 16.8 a and b).

**Definition**

Bronchopulmonary segments are well-defined anatomical segments aerated by tertiary/segmental bronchus. These are pyramidal in shape with apex directed towards hilum and base directed towards periphery having their own arterial supply; but venous drainage is shared by adjacent bronchopulmonary segment.

**Features**

1. These are well-defined anatomic, functional and surgical sectors of the lung.
2. Each one is aerated by a tertiary or segmental bronchus.
3. Each segment is pyramidal in shape with its apex directed towards the root of the lung (Fig. 16.8).

Figs 16.5a–c: Bronchopulmonary segments of the lungs (both sides 1 to 10, see Table 16.3). Medial basal segments are not seen in (b) and (c).
Fig. 16.6: Bronchial tree

Fig. 16.7: Parts of a pulmonary unit

Figs 16.8a and b: The bronchopulmonary segments as seen on: (a) The costal aspects of the right and left lungs. Medial basal segments (no. 7) are not seen, and (b) segments seen on the medial surface of left and right lungs. Lateral segment of middle lobe (no. 4) is not seen on right side.
Each segment has a segmental bronchus, segmental artery, autonomic nerves and lymph vessels. The segmental venules lies in the connective tissue between adjacent pulmonary units of bronchopulmonary segments. During segmental resection, the surgeon works along the segmental veins to isolate a particular segment. 

**Relation to Pulmonary Artery**
The branches of the pulmonary artery accompany the bronchi. The artery lies dorsolateral to the bronchus. Thus each segment has its own separate artery (Fig. 16.9).

**Relation to Pulmonary Vein**
The pulmonary veins do not accompany the bronchi or pulmonary arteries. They run in the intersegmental planes. Thus each segment has more than one vein and each vein drains more than one segment. Near the hilum, the veins are ventromedial to the bronchus.

It should be noted that the bronchopulmonary segment is not a bronchovascular segment because it does not have its own vein.

**Competency achievement:** The student should be able to:

*AN 25.2* Describe development of pleura, lung and heart.

**DEVELOPMENT OF RESPIRATORY SYSTEM**
The lower respiratory tract primordium appears in the third week of intrauterine life in the form of an outgrowth (respiratory diverticulum) from the ventral wall of the primitive pharynx, i.e. the part of the foregut caudal to the hypobranchial eminence. Hence epithelial lining of the respiratory system is endodermal in origin. It forms the lining of the larynx, the trachea, the bronchi and the pulmonary alveoli. The connective tissue, cartilage and smooth muscles of these structures develop from splanchnic mesenchyme surrounding the foregut. As development progresses, the diverticulum separates from the foregut by the tracheo-oesophageal septum (except at the entrance to the larynx).

The respiratory diverticulum below the larynx grows caudally and forms the trachea in the midline. This bifurcates into two lateral outpocketings; the lung buds. In the fifth week of intrauterine life, the proximal parts of each lung bud forms the principal bronchi. Each of these grows laterally and invaginates the pericardio-peritoneal canals (primitive pleural cavities). Following this, the primary bronchi divide into secondary bronchi (3 on the right side and 2 on the left side). These divide dichotomously into tertiary bronchi. Each tertiary bronchus with its surrounding mesenchyme forms a bronchopulmonary segment. By 24th week, about 17 orders of branches are formed and the lung parenchyma develops in four stages.

1. **Pseudoglandular stage** (between 5 and 17 weeks). In this stage, developing lung resembles a gland.
2. **Canalicular stage** (between 16 and 25 weeks), the lumina of bronchi and bronchioles become larger and tissue becomes more vascular.
3. **Terminal sac stage** (between 24 weeks to birth). Many sacules appear at the ends of terminal bronchioles (terminal sacs). Capillaries bulge into these sacs.
4. **Alveolar stage** (late fetal period to 8 years after birth). The epithelial lining of the sacs becomes an extremely thin squamous layer and the alveolocapillary membrane allows exchange of gases.

The four stages overlap each other because the cranial segments of the lungs mature faster than the caudal ones.

By 28–32 weeks, some of the alveolar epithelial cells secrete a substance which is capable of lowering the surface tension at the air–alveolar interface and thus helps maintaining the patency of the alveoli; this is known as pulmonary surfactant.

The four stages overlap each other because the cranial segments of the lungs mature faster than the caudal ones.

**Molecular Regulation**
1. Transcription factor (TBX4) expressed in the endoderm of gut tube at the site of respiratory diverticulum induces formation of lung bud and is responsible for growth and differentiation of lungs.
2. Fibroblast growth factor 10 (FGF10) and other signals from splanchnic mesenchyme probably induces the outgrowth of tracheal bud.
Congenital Anomalies

1. Tracheo-oesophageal fistula: This abnormal communication between the trachea and the oesophagus is due to a deviation of the oesophagotracheal septum or from mechanical factor pushing the dorsal wall of the foregut anteriorly.

2. Tracheal stenosis

3. Azygos lobe of lung around vena azygos: This may be due to an additional respiratory bud which develops independently of the main respiratory system.

4. Hyaline membrane disease or distress syndrome: This is due to a deficiency of pulmonary surfactant.

5. Agenesis of lung.

HISTOLOGY

In a section of the lung, the mesothelial covering of visceral pleura may be visible. The structure of the lung is a lacework of alveoli separated by thin-walled septa. This is traversed by system of intrapulmonary bronchi, bronchioles and alveolar ducts, into which atria, alveolar sacs and alveoli open.

Intrapulmonary Bronchus

Intrapulmonary bronchus is lined by pseudostratified ciliated columnar epithelium with goblet cells resting on a thin basement membrane. Cilia prevent the accumulation of mucus in the bronchial tree. The lamina propria consists of reticular and elastic fibres. The submucous coat contains both mucus and serous acini. A complete layer of smooth muscle fibres is present which is responsible for infoldings of the mucous membrane. Outermost is the hyaline cartilage which is visible as small cartilaginous plates of varying sizes and shapes (Fig. 16.10) with tunica adventitia.

Terminal bronchiole is part of the conducting system of respiratory pathway which is less than 1 mm in diameter. It is lined by simple columnar epithelium. The lamina propria contains elastic and smooth muscle fibres. Both the glands and cartilage plates are absent (Fig. 16.11).

3. Sonic hedgehog (SHH-GLI) and other signaling molecules are involved in the epithelial mesenchyme interaction which governs the branching of tracheal bud and its proliferation.
The main support of the alveoli is provided by elastic fibres. Majority of cells lining the alveoli are the squamous cells or type I pneumocytes. A few cells are larger cells or type II pneumocytes. Type II cells secrete the surfactant which lowers surface tension and prevents alveoli from collapsing.

The interalveolar septum containing numerous capillaries lined by continuous non-fenestrated endothelial cells is present between the adjacent alveoli.

**CLINICAL ANATOMY**

- Usually, the infection of a bronchopulmonary segment remains restricted to it, although tuberculosis and bronchogenic carcinoma may spread from one segment to another.
- Knowledge of the detailed anatomy of the bronchial tree helps considerably in:
  a. Segmental resection (Fig. 16.12).
  b. Visualising the interior of the bronchi through a bronchoscope passed through the mouth and trachea. The procedure is called bronchoscopy.
- Carina is a hook-shaped process projecting backwards from the lower margin of lowest tracheal ring. It helps to divide trachea into two primary bronchi. Right bronchus makes an angle of 25°, while left one makes an angle of 45°. Foreign bodies mostly descend into right bronchus (Fig. 16.13) as it is wider and more vertical than the left bronchus. Enlarged lymph nodes present in this area may distort the carina.
- Carina (Latin **keel**) of the trachea is a sensitive area. When patient is made to lie on her/his left side, secretions from right bronchial tree flow towards the carina due to effect of gravity. This stimulates the cough reflex, and sputum is brought out. This is called **postural drainage** (Fig. 16.14).
Paradoxical respiration: During inspiration, the flail (abnormally mobile) segments of ribs are pulled inside the chest wall while during expiration the ribs are pushed out (Fig. 16.15).

Tuberculosis of lung is one of the commonest diseases. A complete course of treatment must be taken under the guidance of a physician.

Bronchial asthma is a common disease of respiratory system. It occurs due to bronchospasm of smooth muscles in the wall of bronchioles. Patient has difficulty especially during expiration. It is accompanied by wheezing. Epinephrine, a sympathomimetic drug, relieves the symptoms.

Auscultation of lung: Upper lobe is auscultated above 4th rib on both sides; lower lobes are best heard on the back. Middle lobe is auscultated between 4th and 6th ribs on right side.

Superior segment of lower lobe is the most dependent bronchopulmonary segment in supine position. Foreign bodies are likely to be lodged here.

Paradoxical respiration:

A PALM Seed Makes Another Little Palm.

Apical
Posterior
Anterior
Lateral
Medial
Superior
Medial basal
Anterior basal
Lateral basal
Posterior basal

Lung lobes: One having lingula, lobe numbers
Lingula is on Left
The lingula is like an atrophied lobe, so the left lung must have two "other" lobes, and, therefore, right lung has three lobes.

FACTS TO REMEMBER

• Large spongy lungs occupy almost whole of thoracic cage leaving little space for the heart and accompanying blood vessels, etc.
• Bronchopulmonary segments are independent functional units of lung.
• Lungs are subjected to lot of insult by the smoke of cigarette/bidis/pollution.
• Tuberculosis of lung is one of the commonest killer in an underdeveloped or a developing country.

Complete treatment of TB is a must, otherwise the bacteria become resistant to antitubercular treatment. People harbouring resistant bacteria spread the disease to people around through their sputum.
1. Describe the gross anatomy of the lungs. Define a bronchopulmonary segment. Enumerate the segments of the lungs. What is the clinical importance of these segments?

2. Write short notes on:
   a. Comparison of the roots of right and left lungs
   b. Carina of trachea
   c. Postural drainage
   d. Effects of parasympathetic nerves on the lung
   e. Various subdivisions of a segmental bronchus
   f. Intrapulmonary bronchus

---

**Case 1**
A young boy with sore throat while playing with small coins, puts 3 coins in his mouth. When asked by his mother, he takes out two of them, and is not able to take out one.
- Where is the third coin likely to pass?
- What can be the dangers to the boy?

**Ans:** Since the boy was having sore throat, it is likely the coin has been inhaled into his respiratory passages. The coin would pass down the larynx, trachea, right principal bronchus, as it is in line with trachea. The coin further descends into lower lobe bronchus, and into its posterior basal segment. That segment of the lung would get blocked, causing respiratory symptoms.

If the coin goes into oropharynx and oesophagus, it will comfortably travel down whole of digestive tract and would come out in the faecal matter next day.

**Case 2**
A 45-year-old man complained of severe cough, loss of weight, alteration of his voice. He has been smoking for last 25 years. Radiograph of the chest followed by biopsy revealed bronchogenic carcinoma in the left upper lobe of the lung.
- Where did the cancer cells metastasise?
- What caused alteration of his voice?

**Ans:** The bronchogenic carcinoma spreads to the bronchomediastinal lymph nodes. The left supraclavicular nodes are also enlarged and palpable; so these are called ‘sentinal nodes’. The enlarged bronchomediastinal lymph nodes may exert pressure on the left recurrent laryngeal nerve in the thorax causing alteration of voice. The cancer of lung is mostly due to smoking.

**Multiple Choice Questions**

1. Which one of the following structures is not related to medial surface of right lung?
   a. Superior vena cava
   b. Thoracic duct
   c. Trachea
   d. Oesophagus

2. Which of the following structures is single at the root of each lung?
   a. Pulmonary vein
   b. Pulmonary artery
   c. Bronchus
   d. Bronchial artery

3. Which one of the following is not a common relation to the roots of both lungs?
   a. Anterior pulmonary plexus
   b. Pericardiocophrenic vessels
   c. Superior vena cava
   d. Phrenic nerve

4. Part of lung aerated by a respiratory bronchiole is:
   a. A lobule
   b. A segment
   c. Alveolus
   d. Pulmonary unit

5. Respiratory bronchiole ends in all microscopic passages except:
   a. Alveolar ducts
   b. Atria
   c. Pulmonary alveoli
   d. Terminal bronchiole

6. The effects of parasympathetic system on lungs are all, except:
   a. Motor to bronchial muscle
   b. Secretomotor to mucous glands of bronchial tree
   c. Responsible for cough reflex
   d. Causes bronchodilation

7. Which of the following structures run in the intersegmental planes of the lungs?
   a. Segmental venules
   b. Bronchial vessels
   c. Pulmonary arteries
   d. Bronchus

8. Order of origin of segmental bronchi in lower lobe of lung is:
   a. Superior, anterior basal, medial basal, lateral basal and posterior basal
   b. Superior, medial basal, anterior basal and lateral basal and posterior basal
   c. Medial basal, superior, anterior basal, lateral basal and posterior basal
   d. Anterior basal, superior, medial basal, lateral basal and posterior basal

9. Permanent overdistension of alveoli is known as:
   a. Empyema
   b. Emphysema
   c. Pneumothorax
   d. Dyspnkea

10. Angles of right and left bronchi at carina are:
    a. 20° and 40°
    b. 25° and 45°
    c. 40° and 40°
    d. 45° and 25°

**Viva Voce**

- Name the borders and surfaces of lung.
- Name the structures present in the hilum of right lung.
- What is the function of pulmonary ligament?
- What structure arches above the root of left lung?
- Define a bronchopulmonary segment.
- Where do the cartilage and smooth muscle fibres end in the bronchial tree?
- Why does the foreign body mostly enter through the right bronchus?
- Which lobe of lung is auscultated from the posterior aspect of thoracic cage?
- What is postural drainage?
- Which is the most dependent bronchopulmonary segment in supine position?
INTRODUCTION

Mediastinum (plural—mediastina) (Latin *intermediate*) is the middle space left in the thoracic cavity in between the lungs. Its most important content is the heart, enclosed in the pericardium in the middle part of the inferior mediastinum or the middle mediastinum. Above it lies superior mediastinum. Anterior and posterior to the heart are anterior mediastinum and posterior mediastinum, respectively.

The mediastinum is the median septum of the thorax between the two lungs. It includes the mediastinal pleurae.

Competency achievement: The student should be able to:

AN 21.11 Mention boundaries and contents of the superior, anterior, middle and posterior mediastinum.¹

SUPERIOR AND INFERIOR MEDIASTINA

Boundaries

Anteriorly: Sternum
Posteriorly: Vertebral column
Superiorly: Thoracic inlet
Inferiorly: Diaphragm
On each side: Mediastinal pleura.

Divisions

For descriptive purposes, the mediastinum is divided into the *superior mediastinum* and the *inferior mediastinum*. The inferior mediastinum is further divided into the *anterior*, *middle* and *posterior* mediastina (Fig. 17.1).

The superior mediastinum is separated from the inferior by an imaginary plane passing through the sternal angle anteriorly and the lower border of the body of the fourth thoracic vertebra posteriorly. The inferior mediastinum is subdivided into three parts by the pericardium. The area in front of the pericardium is the anterior mediastinum. The area behind the pericardium is the posterior mediastinum. The pericardium and its contents form the middle mediastinum.

DISSECTION

Reflect the upper half of manubrium sterni upwards and study the boundaries and contents of superior and three divisions of the inferior mediastinum.

SUPERIOR MEDIASTINUM

Boundaries

Anteriorly: Manubrium sterni (Fig. 17.1)
Posteriorly: Upper four thoracic vertebrae
Superiorly: Plane of the thoracic inlet
Inferiorly: An imaginary plane passing through the sternal angle in front, and the lower border of the body of the fourth thoracic vertebra behind.

On each side: Mediastinal pleura.

Contents
1 Trachea and oesophagus
2 Muscles: Origins of (i) sternohyoid, (ii) sternothyroid, (iii) lower ends of longus colli.
3 Arteries: (i) Arch of aorta, (ii) brachiocephalic artery, (iii) left common carotid artery, (iv) left subclavian artery (Fig. 17.2).
4 Veins: (i) Right and left brachiocephalic veins, (ii) upper half of the superior vena cava, (iii) left superior intercostal vein.
5 Nerves: (i) Vagus, (ii) phrenic, (iii) cardiac nerves of both sides, (iv) left recurrent laryngeal nerve.
6 Thymus
7 Thoracic duct
8 Lymph nodes: Paratracheal, brachiocephalic, and tracheobronchial.

Superior Mediastinum

The superior mediastinum is divided into—superior, anterior, middle, and posterior mediastina.

Anterior Mediastinum

Anterior mediastinum is a very narrow space in front of the pericardium, overlapped by the thin anterior borders of both lungs. It is continuous through the superior mediastinum with the pretracheal space of the neck. It contains areolar tissue and part of the thymus gland.

Boundaries
Anteriorly: Body of sternum
Posteriorly: Pericardium
Superiorly: Imaginary plane separating the superior mediastinum from the inferior mediastinum.
Inferiorly: Superior surface of diaphragm
On each side: Mediastinal pleura

Contents
1 Sternopericardial ligaments (Fig. 17.1)
2 Lymph nodes with lymphatics
3 Small mediastinal branches of the internal thoracic artery
4 The lowest part of the thymus
5 Areolar tissue.

Middle Mediastinum

Middle mediastinum is occupied by the pericardium and its contents, along with the phrenic nerves and the pericardiacophrenic vessels.

Boundaries
Anteriorly: Sternopericardial ligaments
Posteriorly: Oesophagus, descending thoracic aorta, azygos vein (see Figs 15.2 and 15.3)
On each side: Mediastinal pleura

Contents
1 Heart enclosed in pericardium (Fig. 17.2)
2 Arteries: (i) Ascending aorta, (ii) pulmonary trunk, (iii) two pulmonary arteries (Fig. 17.3)

 Inferior Mediastinum

The inferior mediastinum is divided into—anterior, middle, and posterior mediastina.

Anterior Mediastinum

Anterior mediastinum is a very narrow space in front of the pericardium, overlapped by the thin anterior borders of both lungs. It is continuous through the superior mediastinum with the pretracheal space of the neck. It contains areolar tissue and part of the thymus gland.

Boundaries
Anteriorly: Body of sternum
Posteriorly: Pericardium
Superiorly: Imaginary plane separating the superior mediastinum from the inferior mediastinum.
Inferiorly: Superior surface of diaphragm
On each side: Mediastinal pleura

Contents
1 Sternopericardial ligaments (Fig. 17.1)
2 Lymph nodes with lymphatics
3 Small mediastinal branches of the internal thoracic artery
4 The lowest part of the thymus
5 Areolar tissue.

Middle Mediastinum

Middle mediastinum is occupied by the pericardium and its contents, along with the phrenic nerves and the pericardiacophrenic vessels.

Boundaries
Anteriorly: Sternopericardial ligaments
Posteriorly: Oesophagus, descending thoracic aorta, azygos vein (see Figs 15.2 and 15.3)
On each side: Mediastinal pleura

Contents
1 Heart enclosed in pericardium (Fig. 17.2)
2 Arteries: (i) Ascending aorta, (ii) pulmonary trunk, (iii) two pulmonary arteries (Fig. 17.3)
3 **Veins:** (i) Lower half of the superior vena cava, (ii) terminal part of the azygos vein, and (iii) right and left pulmonary veins.
4 **Nerves:** (i) Phrenic, and (ii) deep cardiac plexus.
5 **Lymph nodes:** Tracheobronchial nodes.

**Posterior Mediastinum**

**Boundaries**

*Anteriorly:* (i) Pericardium, (ii) bifurcation of trachea, (iii) pulmonary vessels, and (iv) posterior part of the upper surface of the diaphragm.

*Posteriorly:* Lower eight thoracic vertebrae and intervening discs.

*On each side:* Mediastinal pleura.

** Contents**

1 **Oesophagus** (Fig. 17.4).
2 **Arteries:** Descending thoracic aorta and its branches.
3 **Veins:** (i) Azygos vein, (ii) hemiazygos vein, and (iii) accessory hemiazygos vein.
4 **Nerves:** (i) Vagi, (ii) splanchnic nerves, greater, lesser and least, arising from the lower eight thoracic ganglia of the sympathetic chain (see Fig. 15.1).

**CLINICAL ANATOMY**

- The prevertebral layer of the deep cervical fascia extends to the superior mediastinum, and is attached to the fourth thoracic vertebra. An infection present in the neck behind this fascia can pass down into the superior mediastinum but not lower down.

  The pretracheal fascia of the neck also extends to the superior mediastinum, where it blends with the arch of the aorta. Neck infections between the pretracheal and prevertebral fasciae can spread into the superior mediastinum, and through it into the posterior mediastinum. Thus mediastinitis can result from infections in the neck.

- There is very little loose connective tissue between the mobile organs of the mediastinum. Therefore, the space can be readily dilated by inflammatory fluids, neoplasms, etc.

- In the superior mediastinum, all large veins are on the right side and the arteries on the left side. During increased blood flow, veins expand enormously, while the large arteries do not expand at all. Thus there is much ‘dead space’ on the right side and it is into this space that tumour or fluids of the mediastinum tend to project (Fig. 17.5).

- Compression of mediastinal structures by any tumour gives rise to a group of symptoms known as *mediastinal syndrome.* The common symptoms are as follows:
  a. Obstruction of superior vena cava gives rise to engorgement of veins in the upper half of the body.
  b. Pressure over the trachea causes dyspnoea, and cough.
  c. Pressure on oesophagus causes dysphagia.
  d. Pressure or the left recurrent laryngeal nerve gives rise to hoarseness of voice (dysphonia).
  e. Pressure on the phrenic nerve causes paralysis of the diaphragm on that side.
  f. Pressure on the intercostal nerves gives rise to pain in the area supplied by them. It is called *intercostal neuralgia.*
Pressure on the vertebral column may cause erosion of the vertebral bodies.

The common causes of mediastinal syndrome are bronchogenic carcinoma, Hodgkin’s disease causing enlargement of the mediastinal lymph nodes, aneurysm or dilatation of the aorta, etc.

**Mnemonics**

**Superior mediastinum contents**: PVT Left

**BATTLE**

Phrenic nerve
Vagus nerve
Thoracic duct
Left recurrent laryngeal nerve (not the right)
Brachiocephalic veins
Aortic arch (and its 3 branches)
Thymus
Trachea
Lymph nodes
Esophagus

**FACTS TO REMEMBER**

- Mediastinum is the middle space between the lungs.
- It is chiefly occupied by the heart enclosed in pericardium with blood vessels and nerves.
- Unit structures in the superior mediastinum are trachea, oesophagus, left recurrent laryngeal nerve between the two tubes and thoracic duct on the left of the oesophagus.

**CLINICOANATOMICAL PROBLEM**

A patient presents with lots of dilated veins in the front of chest and anterior thoracic wall.

- What is the reason for so many veins seen on the anterior body wall?
- How does venous blood go back in circulation?

**Ans:** This appears to be a case of blockage of superior vena cava after the entry of vena azygos. The blood needs to return to heart and it is done through inferior vena cava. The backflow occurs:

   * Superior vena cava blockage → brachiocephalic veins → subclavian veins → axillary veins → lateral thoracic veins → thoracoepigastric veins → superficial epigastric veins → great saphenous veins → femoral veins → common iliac veins → inferior vena cava → right atrium of heart (see Fig. 14.6).

   Many veins open up to assist the drainage.

---

1. Enumerate the boundaries and contents of superior mediastinum.
2. Enumerate the boundaries of mediastinum and its subdivisions.

3. Enumerate:
   a. Contents of middle mediastinum
   b. Contents of posterior mediastinum

### Multiple Choice Questions

1. Boundaries of mediastinum are all, except:
2. Inferior mediastinum is divided into:
   a. Anterior  b. Middle  c. Posterior  d. Posteroinferior
3. Contents of middle mediastinum are all, except:
   a. Heart with pericardium  b. Pulmonary arteries  c. Upper half of superior vena cava  d. Bifurcation of trachea
4. Which one is not a content of superior mediastinum?
   a. Arch of aorta  b. Lower half of superior vena cava  c. Trachea  d. Oesophagus
5. Which one is not a content of posterior mediastinum?

### Viva Voce

- Name the boundaries of superior mediastinum.
- Name the contents of superior mediastinum.
- What are the contents of middle mediastinum?
- What are the contents of posterior mediastinum?
- Which are the ‘unit structures’ in the superior mediastinum?
Pericardium and Heart

INTRODUCTION
Pericardium, comprising fibrous and serous layers, encloses the heart pulsating from ‘womb to tomb’.
Heart is a vital organ, pumping blood to the entire body (Figs 18.1 and 18.2). Its pulsations are governed by the brain through various nerves. Since heartbeat is felt or seen against the chest wall, it appears to be more active than the ‘quiet brain’ controlling it. That is why there are so many songs on the heart and few on the brain. Meditation, yoga and exercise help in regulating the heartbeat through the brain.

Features
The pericardium (Greek around heart) is a fibroserous sac which encloses the heart and the roots of the great vessels. It is situated in the middle mediastinum. It consists of the fibrous pericardium and the serous pericardium (Figs 18.1b and 18.2).
Fibrous pericardium encloses the heart and fuses with the vessels which enter/leave the heart. Heart is situated within the fibrous and serous pericardial sacs. As heart develops, it invaginates itself into the serous sac, without causing any breach in its continuity. The last part to enter is the region of atria, from where the visceral pericardium is reflected as the parietal pericardium. Thus parietal layer of serous pericardium gets adherent to the inner surface of fibrous pericardium, while the visceral layer of serous pericardium gets adherent to the outer layer of heart and forms its epicardium.
On each side, it is related to the mediastinal pleura, the mediastinal surface of the lung, the phrenic nerve, and the pericardiacophrenic vessels. It protects the heart against sudden overfilling and prevents overexpansion of the heart.

SEROUS PERICARDIUM

Serous pericardium is thin, double-layered serous membrane lined by mesothelium. The outer layer or parietal pericardium is fused with the fibrous pericardium. The inner layer or the visceral pericardium, or epicardium is fused to the heart, except along the cardiac grooves, where it is separated from the heart by blood vessels. The two layers are continuous with each other at the roots of the great vessels, i.e. ascending aorta, pulmonary trunk, two venae cavae, and four pulmonary veins.

The pericardial cavity is a potential space between the parietal pericardium and the visceral pericardium. It contains only a thin film of serous fluid which lubricates the apposed surfaces and allows the heart to beat smoothly.

**Sinuses of Pericardium**

The epicardium at the roots of the great vessels is arranged in form of two tubes. The arterial tube encloses the ascending aorta and the pulmonary trunk at the arterial end of the heart tube, and the venous tube encloses the venae cavae and pulmonary veins at the venous end of the heart tube. The passage between the two tubes is known as the transverse sinus of pericardium. During development, to begin with, the veins of the heart are crowded together. As the heart increases in size and these veins separate out, a pericardial reflection surrounds all of them and forms the oblique pericardial sinus. This cul-de-sac is posterior to the left atrium (Fig. 18.4).

The transverse sinus is a horizontal gap between the arterial and venous ends of the heart tube. It is bounded anteriorly by the ascending aorta and pulmonary trunk, and posteriorly by the superior vena cava and inferiorly by the left atrium; on each side, it opens into the general pericardial cavity (Fig. 18.5). It develops from degeneration of the central part of dorsal mesocardium.

The oblique sinus is a narrow gap behind the heart. It is bounded anteriorly by the left atrium, and posteriorly by the parietal pericardium and oesophagus. On the right and left sides, it is bounded by reflections of pericardium as shown in Fig. 18.5. Below and to the left, it opens into the rest of the pericardial cavity. The oblique sinus permits pulsations of the left atrium to take place freely (Figs 18.4 and 18.5). It develops due to rearrangement of veins at the venous end.
PERICARDIUM AND HEART

Contents of Pericardium

1. Heart with cardiac vessels and nerves
2. Ascending aorta
3. Pulmonary trunk
4. Lower half of the superior vena cava
5. Terminal part of the inferior vena cava
6. The terminal parts of the pulmonary veins

Blood Supply

The fibrous and parietal pericardia are supplied by branches from:
1. Internal thoracic arteries
2. Musculophrenic arteries
3. The descending thoracic aorta
4. Veins drain into corresponding veins

Nerve Supply

The fibrous and parietal pericardia are supplied by the phrenic nerves. They are sensitive to pain. The epicardium is supplied by autonomic nerves of the heart and is not sensitive to pain. Pain of pericarditis originates in the parietal pericardium alone. On the other hand, cardiac pain or angina originates in the cardiac muscle or in the vessels of the heart.

Development

Fibrous pericardium develops from septum transversum.

DISSECTION

Make a vertical cut through each side of the pericardium immediately anterior to the line of the phrenic nerve. Join the lower ends of these two incisions by a transverse cut approximately 1 cm above the diaphragm. Turn the flap of pericardium upwards and sideways to examine the pericardial cavity. See that the turned flap comprises fibrous and parietal layer of visceral pericardium. The pericardium enclosing the heart is its visceral layer (Figs 18.2 and 18.3) (refer to BDC App).

Pass a probe from the right side behind the ascending aorta and pulmonary trunk till it appears on the left just to the right of left atrium. This probe is in the transverse sinus of the pericardium (Fig. 18.4).

Lift the apex of the heart upwards. Put a finger behind the left atrium into a cul-de-sac, bounded to the right and below by inferior vena cava and above and to left by lower left pulmonary vein. This is the oblique sinus of pericardium.

Define the borders, surfaces, grooves, apex and base of the heart.

CLINICAL ANATOMY

- Collection of fluid in the pericardial cavity is referred to as pericardial effusion (Fig. 18.6) or

Fig. 18.4: The pericardial cavity seen after removal of the heart. Note the reflections of pericardium, and the mode of formation of the transverse and oblique sinuses

Fig. 18.5: Transverse section through the upper part of the heart. Note that oblique sinus forms posterior boundary of left atrium

Fig. 18.6: Drainage of pericardial effusion
cardiac tamponade. The fluid compresses the heart and restricts venous filling during diastole. It also reduces cardiac output. Pericardial effusion can be drained by puncturing the left fifth or sixth intercostal space just lateral to the sternum, or in the angle between the xiphoid process and left costal margin, with the needle directed upwards, backwards and to the left (Fig. 18.6).

- In mitral stenosis, left atrium enlarges and compresses the oesophagus causing dysphagia.
- During heart surgery, the ligature is passed through the transverse sinus around aorta and the pulmonary trunk.

**HEART**

The heart is a conical hollow muscular organ situated in the middle mediastinum. It is enclosed within the pericardium. It pumps blood to various parts of the body to meet their nutritive requirements. The Greek name for the heart is *cardia* from which we have the adjective *cardiac*. The Latin name for the heart is *cor* from which we have the adjective *coronary*.

The heart is placed obliquely behind the body of the sternum and adjoining parts of the costal cartilages, so that one-third of it lies to the right and two-thirds to the left of the median plane. The direction of blood flow, from atria to the ventricles is downwards, forwards and to the left. The heart measures about 12 × 9 cm and weighs about 300 g in males and 250 g in females.

**EXTERNAL FEATURES**

The human heart has four chambers. These are the right and left atria and the right and left ventricles. The atria (Latin *chamber*) lie above and behind the ventricles. On the surface of the heart, they are separated from the ventricles by an atrioventricular groove. The atria are separated from each other by an interatrial groove. The ventricles are separated from each other by an interventricular groove, which is subdivided into anterior and posterior parts (Fig. 18.7). The heart has:

- An apex directed downwards, forwards and to the left.
- A base (posterior surface) directed backwards
- Three surfaces—antero/sternocostal, inferior and left lateral
- Borders: The surfaces are demarcated by upper, inferior, right and left borders.
For surface marking, see Fig. 21.5.

**Grooves or Sulci**

The atria are separated from the ventricles by a circular atrioventricular or coronary sulcus, which is divided into anterior and posterior parts. Anterior part consists of right and left halves. Right half is oblique between right auricle and right ventricle, lodging right coronary artery. Left part is small between left auricle and left ventricle, lodges circumflex branch of left coronary artery.

The coronary sulcus is overlapped anteriorly by the ascending aorta and the pulmonary trunk. The interatrial groove is faintly visible posteriorly, while anteriorly, it is hidden by the aorta and pulmonary trunk. The anterior interventricular groove is nearer to the left margin of the heart. It runs downwards and to the left. The lower end of the groove separates the apex from the rest of the inferior border of the heart. The posterior interventricular groove is situated on the diaphragmatic or inferior surface of the heart. It is nearer to the right margin of this surface (Figs 18.8a and b). The two interventricular grooves meet at the inferior border near the apex.

**Apex of the Heart**

Apex of the heart is formed entirely by the left ventricle. It is directed downwards, forwards and to the left and is overlapped by the anterior border of the left lung. It is situated in the left fifth intercostal space 9 cm lateral to the midsternal line just medial to the midclavicular line. In the living subject, pulsations may be seen and felt over this region (Fig. 18.7).

In children below 2 years, apex is situated in the left fourth intercostal space in midclavicular line.

**CLINICAL ANATOMY**

Normally, the cardiac apex or apex beat is on the left side. In the condition called dextrocardia, the apex is on the right side (Fig. 18.9). Dextrocardia may
be part of a condition called *situs inversus* in which all thoracic and abdominal viscera are a mirror image of normal.

**Base of the Heart**

The *base* of the heart is also called its posterior surface. It is formed mainly by the left atrium and by a small part of the right atrium.

In relation to the base, one can see the openings of four pulmonary veins which open into the left atrium; and of the superior and inferior venae cavae (Latin, *empty vein*) which open into the right atrium. It is related to thoracic five to thoracic eight vertebrae in the lying posture, and descends by one vertebra in the erect posture. It is separated from the vertebral column by the pericardium, the right pulmonary veins, the oesophagus and the aorta (see Figs 15.3 and 17.2).

**Borders of the Heart**

1. The *upper border* is slightly oblique, and is formed by the two atria, chiefly the left atrium.
2. The *right border* is more or less vertical and is formed by the right atrium. It extends from superior vena cava to inferior vena cava (IVC).
3. The *inferior border* is nearly horizontal and is formed mainly by the right ventricle. A small part of it near the apex is formed by left ventricle. It extends from IVC to apex.
4. The *left border* is oblique and curved. It is formed mainly by the left ventricle, and partly by the left auricle. It separates the anterior and left surfaces of the heart (Fig. 18.7). It extends from apex to left auricle.

**Surfaces of the Heart**

The *anterior* or *sternocostal surface* is formed mainly by the right atrium and right ventricle, and partly by the left ventricle and left auricle (Fig. 18.7). The left atrium is not seen on the anterior surface as it is covered by the aorta and pulmonary trunk. Most of the sternocostal surface is covered by the lungs, but a part of it that lies behind the cardiac notch of the left lung is uncovered. The uncovered area is dull on percussion. Clinically, it is referred to as the *area of superficial cardiac dullness*.

The *inferior* or *diaphragmatic surface* rests on the central tendon of the diaphragm. It is formed in its left two-thirds by the left ventricle, and in its right one-third by the right ventricle. It is traversed by the

posterior interventricular groove, and is directed downwards and slightly backwards (Fig. 18.8).

The left surface is formed mostly by the left ventricle, and at the upper end by the left auricle. In its upper part, the surface is crossed by the coronary sulcus. It is related to the left phrenic nerve, the left peri-
cardiacophrenic vessels and the pericardium.

Crux of the Heart
Crux of the heart is the meeting point of interatrial, atrioventricular and posterior interventricular grooves.

Types of Circulation
There are two main types of circulations—systemic and pulmonary. Table 18.1 shows their comparison.

Competency achievement: The student should be able to:
AN 22.2 Describe and demonstrate external and internal features of each chamber of heart.

External Features
1. The chamber is elongated vertically, receiving the superior vena cava at the upper end and the inferior vena cava at the lower end (Fig. 18.11).
2. The upper end is prolonged to the left to form the right auricle (Latin little ear). The auricle covers the root of the ascending aorta and partly overlaps the infundibulum of the right ventricle. Its margins are notched and the interior is sponge-like, which prevents free flow of blood.
3. Along the right border of the atrium, there is a shallow vertical groove which passes from the superior vena cava to the inferior vena cava. This groove is called the sulcus terminalis. It is produced by an internal muscular ridge called the crista terminalis (Fig. 18.11a). The upper part of the sulcus contains the sinuatrial or SA node which acts as the pacemaker of the heart.
4. The right atrioventricular groove separates the right atrium from the right ventricle. It is more or less vertical and lodges the right coronary artery and the small cardiac vein.
**Tributaries or Inlets of the Right Atrium**

1. Superior vena cava
2. Inferior vena cava
3. Coronary sinus
4. Anterior cardiac veins
5. Venae cordis minimae (thebesian veins)
6. Sometimes the right marginal vein

**Right Atrioventricular Orifice**

Blood passes out of the right atrium through the right atrioventricular or tricuspid orifice and goes to the right ventricle. The tricuspid orifice is guarded by the tricuspid valve which maintains unidirectional flow of blood (Fig. 18.11b).

**Internal Features**

The interior of the right atrium can be broadly divided into the following three parts:
**Smooth Posterior Part or Sinus Venarum**

1. Developmentally, it is derived from the right horn of the sinus venosus.
2. Most of the tributaries except the anterior cardiac veins open into it.
   a. The superior vena cava opens at the upper end.
   b. The inferior vena cava opens at the lower end (Fig. 18.11a).
      The opening of inferior vena cava is guarded by a rudimentary valve of the inferior vena cava or *Eustachian valve*. During embryonic life, the valve guides the inferior vena caval blood to the left atrium through the *foramen ovale*.
   c. The coronary sinus opens between the opening of the inferior vena cava and the right atrioventricular orifice. The opening is guarded by the *valve of the coronary sinus or thebesian valve*.
   d. The venae cordis minimae are numerous small veins present in the walls of all the four chambers. They open into the right atrium through small foramina.
3. The *intervenous tubercle of Lower* is a very small projection, scarcely visible, on the posterior wall of the atrium just below the opening of the superior vena cava. During embryonic life, it directs the superior caval blood to the right ventricle.

**Rough Anterior Part or Pectinate Part, including the Auricle**

1. Developmentally, it is derived from the primitive atrial chamber.
2. It presents a series of transverse muscular ridges called *musculi pectinati* (Figs 18.11a and b).
   They arise from the crista terminalis and run forwards and downwards towards the atrioventricular orifice, giving the appearance of the teeth of a comb. In the auricle, the muscles are interconnected to form a reticular network.

**Interatrial Septum**

1. Developmentally, it is derived from the *septum primum* and *septum secundum*.
2. It presents the *fossa ovalis*, a shallow saucer-shaped depression, in the lower part. The fossa represents the site of the embryonic septum primum.
3. The *annulus ovalis or limbus* (Latin a border) *fossa ovalis* is the prominent margin of the fossa ovalis. It represents the lower free edge of the septum secundum. It is distinct above and at the sides of the fossa ovalis, but is deficient inferiorly. Its anterior edge is continuous with the left end of the valve of the inferior vena cava.
4. The remains of the *foramen ovale* are occasionally present. This is a small slit-like valvular opening between the upper part of the fossa and the limbus. It is normally occluded after birth, but may sometimes persist.

**RIGHT VENTRICLE**

**Position**

The right ventricle is a triangular chamber which receives blood from the right atrium and pumps it to the lungs through the pulmonary trunk and pulmonary arteries. It forms the inferior border and two-thirds part of the sternocostal surface and one-third part of inferior surface of the heart (Fig. 18.7).
External Features

1. Externally, the right ventricle has two surfaces—
   anterior or sternocostal and inferior or diaphragmatic.

2. The interior has two parts:
   a. The inflowing part is rough due to the presence of
      muscular ridges called trabeculae carneae. It
      develops from the proximal part of bulbus cordis
      of the heart tube.
   b. The outflowing part or infundibulum is smooth
      and forms the upper conical part of the right
      ventricle which gives rise to the pulmonary trunk.
      It develops from the midportion of the bulbus
      cordis.

   The two parts are separated by a muscular ridge called
   the supraventricular crest or infundibuloventricular crest
   situated between the tricuspid and pulmonary orifices.

Internal Features

1. The interior shows two orifices:
   a. The right atrioventricular or tricuspid orifice, guarded by the tricuspid valve.
   b. The pulmonary orifice guarded by the pulmonary valve (Figs. 18.12a and b).

2. The interior of the inflowing part shows trabeculae carneae or muscular ridges of three types:
   a. Ridges or fixed elevations
   b. Bridges
   c. Pillars or papillary muscles with one end attached
      to the ventricular wall, and the other end
      connected to the cusps of the tricuspid valve by
      chordae tendineae (Latin strings to stretch). There
      are three papillary muscles in the right ventricle—
      anterior, posterior and septal. The anterior muscle
      is the largest (Fig. 18.12). The posterior or inferior
      muscle is small and irregular. The septal muscle is
      divided into a number of little nipples. Each papillary
      muscle is attached by chordae tendineae to the
      contiguous sides of two cusps (Fig. 18.13).

   3. The septomarginal trabecula or moderator band is a
      muscular ridge extending from the ventricular
      septum to the base of the anterior papillary muscle.
      It contains the right branch of the AV bundle
      (Figs. 18.12 and 18.14).

   4. The cavity of the right ventricle is crescentic in section
      because of the forward bulge of the interventricular
      septum (Fig. 18.15).

   5. The wall of the right ventricle is thinner than that of
      the left ventricle in a ratio of 1:3.

Interventricular Septum

The septum is placed obliquely. Its one surface faces
forwards and to the right and the other faces backwards.
Thorax

Section 2

Fig. 18.15: Schematic transverse section through the ventricles of the heart showing the atrioventricular orifices, papillary muscles, and the pulmonary and aortic orifices

and to the left. The upper part of the septum is thin and membranous and separates not only the two ventricles but also the right atrium and left ventricle. The lower part is thick muscular and separates the two ventricles (Fig. 18.15). Its position is indicated by the anterior and posterior interventricular grooves.

**DISSECTION**

Incise along the ventricular aspect of right AV groove, till you reach the inferior border. Continue to incise along the inferior border till the inferior end of anterior interventricular groove. Next cut along the infundibulum.

Now the anterior wall of right ventricle is reflected to the left to study its interior (Fig. 18.10) (Refer to BDC App).

**LEFT ATRIUM**

**Position**

The left atrium is a quadrangular chamber situated posteriorly. Its appendage, the *left auricle* projects anteriorly to overlap the infundibulum of the right ventricle. The left atrium forms the left two-thirds of the base of the heart, the greater part of the upper border, parts of the sternocostal and left surfaces and the left border. It receives oxygenated blood from the lungs through four pulmonary veins, and pumps it to the left ventricle through the left atrioventricular or bicuspid (Latin *two tooth point*) or mitral orifice (Latin *like bishop’s mitre*) which is guarded by the valve of the same name.

**Features**

1. The posterior surface of the atrium forms the anterior wall of the oblique sinus of pericardium (Fig. 18.5).
2. The anterior wall of the atrium is formed by the interatrial septum.
3. Two pulmonary veins open into the atrium on each side of the posterior wall (Fig. 18.8).
4. The greater part of the interior of the atrium is smooth walled. It is derived embryologically from the
absorbed pulmonary veins which open into it. Musculi pectinati are present only in the auricle where they form a reticulum. This part develops from the original primitive atrial chamber of the heart tube. The septal wall shows the fossa lunata corresponding to the fossa ovalis of the right atrium. In addition to the four pulmonary veins, the tributaries of the atrium include a few venae cordis minimae.

Table 18.2 compares the right atrium and the left atrium.

**LEFT VENTRICLE**

**Position**

The left ventricle receives oxygenated blood from the left atrium and pumps it into the aorta. It forms the apex of the heart, a part of the sternocostal surface, most of the left border and left surface, and the left two-thirds of the diaphragmatic surface (Figs 18.7 and 18.8).

**Features**

1.Externally, the left ventricle has three surfaces—anteri or sternocostal, inferior or diaphragmatic, and left.
2. The interior is divisible into two parts:
   a. The lower rough part with trabeculae carneae develops from the primitive ventricle of the heart tube (Fig. 18.16).
   b. The upper smooth part or aortic vestibule gives origin to the ascending aorta: It develops from the
midportion of the bulbus cordis. The vestibule lies between the membranous part of the interventricular septum and the anterior or aortic cusp of the mitral valve.

3 The interior of the ventricle shows two orifices:
a. The left atrioventricular or bicuspid or mitral orifice, guarded by the bicuspid or mitral valve.
b. The aortic orifice, guarded by the aortic valve (Fig. 18.15).

4 There are two well-developed papillary muscles— anterior and posterior. Chordae tendineae from both muscles are attached to both the cusps of the mitral valve.

5 The cavity of the left ventricle is circular in cross-section (Fig. 18.15).

6 The walls of the left ventricle are three times thicker than those of the right ventricle. Table 18.3 compares the right and left ventricle.

**DISSECTION**

Open the left ventricle by making a bold incision on the ventricular aspect of atrioventricular groove below left auricle and along whole thickness of left ventricle from above downwards till its apex. Curve the incision towards right till the inferior end of anterior interventricular groove. Reflect the flap to the right and clean the atrioventricular and aortic valves (Fig. 18.15).

Remove the surface layers of the myocardium. Note the general directions of its fibres and the depth of the coronary sulcus, the wall of the atrium passing deep to the bulging ventricular muscle. Dissect the musculature and the conducting system of the heart (refer to BDC App).

**CLINICAL ANATOMY**

• The area of the chest wall overlying the heart is called the precordium.

• Rapid pulse or increased heart rate is called tachycardia (Greek rapid heart).

• Slow pulse or decreased heart rate is called bradycardia (Greek slow heart).

• Irregular pulse or irregular heart rate is called arrhythmia.

• Consciousness of one’s heartbeat is called palpitation.

• Inflammation of the heart can involve more than one layer of the heart. Inflammation of the pericardium is called pericarditis; of the myocardium is myocarditis; and of the endocardium is endocarditis.

• Normally, the diastolic pressure in ventricles is zero. A positive diastolic pressure in the ventricle is evidence of its failure. Any one of the four chambers of the heart can fail separately, but ultimately the rising back pressure causes right-sided failure (congestive cardiac failure or CCF) which is associated with increased venous pressure, oedema on feet, and breathlessness on exertion. Heart failure (right sided) due to lung disease is known as cor pulmonale.

**STRUCTURE OF HEART**

**VALVES**

The valves of the heart maintain unidirectional flow of the blood and prevent its regurgitation in the opposite direction. There are two pairs of valves in the heart, a pair of atrioventricular valves and a pair of semilunar valves. The right atrioventricular valve is known as the tricuspid valve because it has three cusps. The left atrioventricular valve is known as the bicuspid valve because it has two cusps. It is also called the mitral valve. The semilunar valves include the aortic and pulmonary valves, each having three semilunar cusps. The cusps are folds of endocardium, strengthened by an intervening layer of fibrous tissue (Figs 18.17a and b).

**Atrioventricular Valves**

1. Both valves are made up of the following components.
   a. A *fibrous ring* to which the cusps are attached (Fig. 18.13).
   b. The *cusps* are flat and project into the ventricular cavity. Each cusp has an attached and a free margin, and an atrial and a ventricular surface. The atrial surface is smooth (Fig. 18.16). The free margins and ventricular surfaces are rough and irregular due to the attachment of chordae tendineae. The valves are closed during ventricular systole (Greek contraction) by apposition of the atrial surfaces near the serrated margins (Fig. 18.15).
   c. The *chordae tendineae* connect the free margins and ventricular surfaces of the cusps to the apices of the papillary muscles. They prevent eversion of the free margins and limit the amount of ballooning of the cusps towards the cavity of the atrium.
   d. The atrioventricular valves are kept competent by active contraction of the *papillary muscles*, which pull on the chordae tendineae during ventricular systole. Each papillary muscle is connected to the contiguous halves of two cusps (Fig. 18.13).

2. Blood vessels are present only in the fibrous ring and in the basal one-third of the cusps. Nutrition to the central two-thirds of the cusps is derived directly from the blood in the cavity of the heart.

3. The tricuspid valve has three cusps can admit the tips of three fingers. The three cusps—the anterior, posterior or inferior, and septal. These lie against the three walls of the ventricle. Of the three papillary muscles, the anterior is the largest, the inferior is smaller and irregular, and the septal is represented by a number of small muscular elevations.

4. The mitral or bicuspid valve has two cusps—a large anterior or aortic cusp, and a small posterior cusp. It admits the tips of two fingers. The anterior cusp lies between the mitral and aortic orifices. The mitral cusps are smaller and thicker than those of the tricuspid valve.
   For surface marking of valves, see Fig. 21.6.

**Semilunar Valves**

1. The aortic and pulmonary valves are called semilunar valves because their cusps are semilunar in shape. Both valves are similar to each other (Figs 18.17a and b).
2. Each valve has three cusps which are attached directly to the vessel wall, there being no fibrous ring. The cusps form small pockets with their mouths directed away from the ventricular cavity. The free margin of each cusp contains a central fibrous *nodule* from each side of which a thin smooth margin the *lunule* extends up to the base of the cusp. These valves are closed during ventricular diastole when each cusp bulges towards the ventricular cavity (Fig. 18.17).
3. Opposite the cusps, the vessel walls are slightly dilated to form the aortic and pulmonary sinuses. The coronary arteries arise from the anterior and the left posterior aortic sinuses (Fig. 18.18).
   For surface marking, see Fig. 21.6.

**Clinical Anatomy**

- The first heart sound is produced by closure of the atrioventricular valves. The second heart sound is produced by closure of the semilunar valves (Figs 18.19a and b).
- Narrowing of the valve orifice due to fusion of the cusps is known as ‘stenosis’, viz. mitral stenosis, aortic stenosis, etc.
Dilatation of the valve orifice, or stiffening of the cusps causes imperfect closure of the valve leading to backflow of blood. This is known as incompetence or regurgitation, e.g. aortic incompetence or aortic regurgitation.

**FIBROUS SKELETON**

The fibrous rings surrounding the atroventricular and arterial orifices, along with some adjoining masses of fibrous tissue, constitute the fibrous skeleton of the heart. It provides attachment to the cardiac muscle and keeps the cardiac valves competent (Fig. 18.20).

The atrioventricular fibrous rings are in the form of the figure of 8. The atria, the ventricles and the membranous part of the interventricular septum are attached to them. There is no muscular continuity between the atria and ventricles across the rings except for the atrioventricular bundle or bundle of His.

There is large mass of fibrous tissue between the atrioventricular rings behind and the aortic ring in front. It is known as the trigonum fibrosum dextrum. In some mammals, like sheep, a small bone the os cordis is present in this mass of fibrous tissue.

Another smaller mass of fibrous tissue is present between the atrioventricular rings behind and the aortic ring in front. It is known as the trigonum fibrosum sinistrum. The tendon of the infundibulum (close to pulmonary valve) binds the posterior surface of the infundibulum to the aortic ring.

**MUSCULATURE OF THE HEART**

Cardiac muscle fibres form long loops which are attached to the fibrous skeleton. Upon contraction of the muscular loops, the blood from the cardiac chambers is wrung out like water from a wet cloth. The atrial fibres are arranged in a superficial transverse layer and a deep anteroposterior (vertical) layer.

The ventricular fibres are arranged in superficial and deep layers.

The superficial fibres arise from skeleton of the heart to undergo a spiral course. First these pass across the inferior surface, wind round the lower border and then...
CONDUCTING SYSTEM

The conducting system is made up of myocardium that is specialised for initiation and conduction of the cardiac impulse. Its fibres are finer than other myocardial fibres, and are completely cross-striated. The conducting system has the following parts.

1 **Sinuatrial node or SA node:** It is known as the ‘pacemaker’ of the heart. It generates impulses at the rate of about 70–100 beats/min and initiates the heartbeat. It is horseshoe-shaped and is situated at the atrio caval junction in the upper part of the sulcus terminals. The impulse travels through the atrial wall to reach the AV node (Fig. 18.14).

**Competency achievement:** The student should be able to:

**AN 22.7** Mention the parts, position and arterial supply of the conducting system of heart.
2. **Atrioventricular node or AV node**: It is smaller than the SA node and is situated in the lower and dorsal part of the atrial septum just above the opening of the coronary sinus. It is capable of generating impulses at a rate of about 40 to 60 beats/minute.

3. **Atrioventricular bundle or AV bundle or bundle of His**: It is the only muscular connection between the atrial and ventricular musculatures. It begins as the atrioventricular (AV) node crosses AV ring and descends along the posteroinferior border of the membranous part of the ventricular septum. At the upper border of the muscular part of the septum, it divides into right and left branches.

4. **The right branch** of the AV bundle passes down the right side of the interventricular septum. A large part enters the moderator band to reach the anterior wall of the right ventricle where it divides into Purkinje fibres.

5. **The left branch** of the AV bundle descends on the left side of the interventricular septum and is distributed to the left ventricle after dividing into Purkinje fibres.

6. **The Purkinje fibres** form a subendocardial plexus. They are large pale fibres striated only at their margins. They usually possess double nuclei. These generate impulses at the rate of 20–35 beats/minute.

**Blood supply**: Whole of conducting system except left branch of AV bundle is supplied by right coronary artery. In 40% cases, left coronary artery supplies SA node.

### Features of Coronary Arteries

i. The blood flows through these arteries during diastole of heart.

ii. Diameter is 1.5–5.2 mm.

iii. Left coronary is larger in calibre and supplies more myocardium.

iv. These arteries are ‘functional end arteries’. Though their branches anastomose with each other but one cannot compensate for the other artery in case of thrombosis.

v. The origin of posterior interventricular artery determines the dominance of the artery.

vi. Sympathetic stimulation dilates the intramuscular arteries and constricts the epicardial arteries.

### RIGHT CORONARY ARTERY

**Position**

Right coronary artery is smaller than the left coronary artery. It arises from the anterior aortic sinus (Figs 18.22a and b) of ascending aorta.

**Course**

1. It first passes forwards and to the right to emerge on the surface of the heart between the root of the pulmonary trunk and the right auricle.

2. It then runs downwards in the right anterior coronary sulcus to the junction of the right and inferior borders of the heart.

3. It winds round the inferior border to reach the diaphragmatic surface of the heart. Here it runs backwards and to the left in the right posterior coronary sulcus to reach the posterior interventricular groove.

4. It terminates by anastomosing with the circumflex branch of left coronary artery at the crux.

**Branches**

- Atrial branches are anterior, posterior and lateral. One of the anterior atrial branches is called SA nodal artery. It arises from right coronary artery in 60% cases.
- Right conus artery forms an arterial circle around pulmonary trunk with a similar branch from the left coronary artery. The circle is called, ‘annulus of Vieussens’.
- Ventricular branches are as anterior and posterior groups. The anterior group lies on the sternocostal surface while posterior group traverses the diaphragmatic surface of the heart.
- Right marginal artery arises as the right coronary artery crosses the right border of heart. It runs along its inferior border till the apex of heart.
DISSECTION

Carefully remove the fat from the coronary sulcus. Identify the right coronary artery in the depth of the right part of the atroventricular sulcus (Figs 18.22a and b).

Trace the right coronary artery superiorly to its origin from the right aortic sinus and inferiorly till it turns onto the posterior surface of the heart to lie in its atroventricular sulcus. It gives off the posterior interventricular branch which is seen in posterior interventricular groove.

The right coronary artery ends by anastomosing with the circumflex branch of left coronary artery or by dipping itself deep in the myocardium there.

LEFT CORONARY ARTERY

Position

Left coronary artery is larger than the right coronary artery. It arises from the left posterior aortic sinus of ascending aorta.

Course

1. The artery first runs forwards and to the left and emerges between the pulmonary trunk and the left auricle. Here it gives the anterior interventricular branch which runs downwards in the groove of the same name. The further continuation of the left coronary artery is called the circumflex artery (Figs 18.22a and 18.23).
2. After giving off the anterior interventricular branch, the artery runs to the left in the left anterior coronary sulcus.

Area of Distribution

1. Right atrium
2. Ventricles:
   a. Greater part of the right ventricle, except the area adjoining the anterior interventricular groove.
   b. A small part of the left ventricle adjoining the posterior interventricular groove.
3. Posterior one-third part of the interventricular septum.
4. Whole of the conducting system of the heart except a part of the left branch of the AV bundle. The SA node is supplied by the left coronary artery in about 40% of cases.

Figs 18.22a and b: Arterial supply of heart: (a) Sternocostal surface, and (b) diaphragmatic surface

- Posterior interventricular branch arises close to the crux of heart and lies in the posterior interventricular groove. It gives septal branches to posterior one-third of interventricular septum. It also supplies AV node.

Fig. 18.23: Origin of the coronary arteries from the aortic sinuses and their course in the coronary sulcus, as seen after removal of the atria (anatomical position)
In about 10% of hearts, the right coronary is rather small and is not able to give the posterior interventricular branch. In these cases, the circumflex artery, the continuation of the left coronary, provides the posterior interventricular branch as well as to the AV node. Such cases are called left dominant. Mostly, the right coronary gives posterior interventricular artery. Such hearts are right dominant. Thus the artery giving the posterior interventricular branch is the dominant artery.

### Collateral Circulation

#### Cardiac Anastomoses

The two coronary arteries anastomose with each other in myocardium.

#### Extracardiac Anastomoses

The coronary arteries anastomose with the following.
1. Vasa vasorum of the aorta
2. Vasa vasorum of the pulmonary arteries
3. The internal thoracic arteries
4. The bronchial arteries
5. The pericardiocaphreatic arteries

The last three anastomose through the pericardium. These channels may open up in emergencies when both coronary arteries are obstructed.

Retrograde flow of blood in the veins may irrigate the myocardium.

These anastomoses are of little practical value. They are not able to provide an alternative source of blood in case of blockage of a branch of a coronary artery. Blockage of arteries or coronary thrombosis usually leads to death of myocardium. The condition is called myocardial infarction.
VEINS OF THE HEART

These are the great cardiac vein, the middle cardiac vein, the right marginal vein, the posterior vein of the left ventricle, the oblique vein of the left atrium, the anterior cardiac veins, and the venae cordis minimae.

Fig. 18.26: Pain of angina pectoris felt in precordium and along medial border of left arm.

Fig. 18.25: Myocardial infarction due to blockage of anterior interventricular branch of left coronary artery.

Fig. 18.27: Stent passed in the blocked coronary artery.

Fig. 18.28: Grafts put beyond the site of blockage.

Competency achievement: The student should be able to:
AN 22.4 Describe anatomical basis of ischaemic heart disease.

CLINICAL ANATOMY

- Thrombosis of coronary artery is a common cause of sudden death in persons past middle age. This is due to myocardial ischaemia infarction and ventricular fibrillation (Fig. 18.25).

- Incomplete obstruction, usually due to spasm of the coronary artery causes angina pectoris, which is associated with agonising pain in the precordial region and down the medial side of the left arm and forearm (Fig. 18.26). Pain gets relieved by putting appropriate tablets below the tongue.

- Coronary angiography determines the site(s) of narrowing or occlusion of the coronary arteries or their branches.

- Angioplasty helps in removal of small blockage. It is done using small stent or small inflated balloon (Fig. 18.27) through a catheter passed upwards through the femoral artery, aorta, into the coronary artery.

- If there are large segments or multiple sites of blockage, coronary bypass is done using either great saphenous vein or internal thoracic artery as graft(s) (Fig. 18.28).
Coronary Sinus

The coronary sinus is the largest vein of the heart. It is situated in the left posterior coronary sulcus. It is about 3 cm long. It ends by opening into the posterior wall of the right atrium. It receives the following tributaries:

1. The great cardiac vein accompanies the anterior interventricular artery and then the circumflex artery to enter the left end of the coronary sinus (Fig. 18.29a). It receives the left marginal vein from the left ventricle.

2. The middle cardiac vein accompanies the posterior interventricular artery, and joins the middle part of the coronary sinus.

3. The small cardiac vein accompanies the right coronary artery in the right posterior coronary sulcus and joins the right end of the coronary sinus. The right marginal vein may drain into the small cardiac vein (Fig. 18.29b).

4. The posterior vein of the left ventricle runs on the diaphragmatic surface of the left ventricle and ends in the coronary sinus.

5. The oblique vein of the left atrium of Marshall is a small vein running on the posterior surface of the left atrium. It terminates in the left end of the coronary sinus. It develops from the left common cardinal vein or duct of Cuvier which may sometimes form a large left superior vena cava.

6. The right marginal vein accompanies the marginal branch of the right coronary artery. It may either drain into the small cardiac vein, or may open directly into the right atrium.

Anterior Cardiac Veins

The anterior cardiac veins are three or four small veins which run parallel to one another on the anterior wall of the right ventricle and usually open directly into the right atrium through its anterior wall.

Venae Cordis Minimae

The venae cordis minimae or thebesian veins or smallest cardiac veins are numerous small valveless veins present in all four chambers of the heart which open directly into the cavity. These are more numerous on the right side of the heart than on the left. This may be one reason why left-sided infarcts are more common.

LYMPHATICS OF HEART

Lymphatics of the heart accompany the coronary arteries and form two trunks. The right trunk ends in the brachiocephalic nodes, and the left trunk ends in the tracheobronchial lymph nodes at the bifurcation of the trachea.

NERVE SUPPLY OF HEART

Parasympathetic nerves reach the heart via the vagus. These are cardioinhibitory; on stimulation, they slow down the heart rate.

Sympathetic nerves are derived from the upper four to five thoracic segments of the spinal cord. These are cardioacceleratory, and on stimulation, they increase the heart rate, and also dilate the coronary arteries.
Both parasympathetic and sympathetic nerves form the superficial and deep cardiac plexuses, the branches of which run along the coronary arteries to reach the myocardium.

The superficial cardiac plexus is situated below the arch of the aorta in front of the right pulmonary artery. It is formed by:

a. The superior cervical cardiac branch of the left sympathetic chain.

b. The inferior cervical cardiac branch of the left vagus nerve.

The plexus is connected to the deep cardiac plexus, right coronary artery, and to the left anterior pulmonary plexus (Fig. 18.30).

The deep cardiac plexus is situated in front of the bifurcation of the trachea, and behind the arch of the aorta. It is formed by all the cardiac branches derived from all the cervical and upper thoracic ganglia of the sympathetic chain, and the cardiac branches of the vagus and recurrent laryngeal nerves, except those which form the superficial plexus. The right and left halves of the plexus distribute branches to the corresponding coronary and pulmonary plexuses. Separate branches are given to the atria.

### CLINICAL ANATOMY

- Cardiac pain is an ischaemic pain caused by incomplete obstruction of a coronary artery.

- Axons of pain fibres conveyed by the sensory sympathetic cardiac nerves reach thoracic one to thoracic five segments of spinal cord mostly through the dorsal root ganglia of the left side. Since these dorsal root ganglia also receive sensory impulses from the medial side of arm, forearm and upper part of front of chest, the pain gets referred to these areas as depicted in Fig. 18.26.

- Viscera have low amount of sensory output whereas skin is an area of high amount of sensory output. So pain arising from area of low sensory output area is projected as coming from high sensory output area.

### Competency achievement: The student should be able to:

**AN 25.2** Describe development of respiratory system and heart.

Development of respiratory system has been described in Chapter 16 and development of heart has been described in this chapter.

### DEVELOPMENTAL COMPONENTS

1. **Right atrium** (Fig. 18.11)
   a. Rough anterior part—atrial chamber proper.
   b. Smooth posterior part:
      - Absorption of right horn of sinus venosus
      - Interatrial septum
      - Demarcating part—crista terminalis.
2 Left atrium (Figs 18.16 and 18.29b)
   a. Rough part—atrial chamber proper
   b. Smooth part:
      – Absorption of pulmonary veins.
      – Interatrial septum.

3 Right ventricle
   a. Rough part—proximal portion of bulbus cordis (Fig. 18.12).
   b. Smooth part—the conus cordis or middle portion of bulbus cordis.

4 Left ventricle (Fig. 18.16)
   a. Rough part—whole of primitive ventricular chamber.
   b. The conus cordis or the middle portion of bulbus cordis forms the smooth part.

5 Interatrial septum
   a. Septum primum—fossa ovalis.
   b. Septum secundum—limbus fossa ovalis.

6 Interventricular septum
   a. Thick muscular in lower part by the two ventricles.
   b. Thin membranous in upper part by fusion of inferior atrioventricular cushion and right and left conus swelling. Membranous part not only separates the two ventricles, but also separates right atrium from left ventricle.

7 Truncus arteriosus or distal part of bulbus cordis forms the ascending aorta and pulmonary trunk, as separated by spiral septum.
   Spiral septum is responsible for triple relation of ascending aorta, arch of aorta and descending thoracic and descending abdominal aortae. The last mentioned vessel divides into common iliac arteries. Each common iliac artery terminates by dividing into external and internal iliac arteries. Arising from two internal iliac arteries are the two umbilical arteries which in turn pass through the umbilical cord to end in the placenta.

   Heart is fully functional at the end of second month of intrauterine life.

**MOLECULAR REGULATION OF CARDIAC DEVELOPMENT**

The genes involved in cardiac development are Nirenberg and Kim 2 Homeobox 5 (NKX-2). This is the master gene regulating development of heart.

Heart and neural crest derivative 1 (HAND-1) and HAND-2 are other genes involved in development of the ventricles.

Signaling molecules involved are bone morpho-
genic proteins (BMP’s 2 and 4) secreted by the endoderm and lateral plate mesoderm which induce the heart forming region of splanchnic mesoderm.

Crescent and cerebrus produced by endoderm cells inhibit WNT proteins 3a and 8 secreted by neural tube which inhibit heart development. Thus cardiac development proceeds uninhibited. Cardiac looping is dependent on lefty 2. TBX 5 is important for septation.

**FOETAL CIRCULATION**

The foetus (Greek offspring) is dependent for its entire nutrition on the mother, and this is achieved through the placenta attached to the uterus. As the lungs are not functioning, the blood needs to bypass the pulmonary circuit. The oxygenated blood reaches the foetus through the single ‘umbilical vein’. This vein containing oxygenated blood traverses the umbilical cord to reach the liver. The oxygenated blood bypasses the liver via ‘the ductus venosus’ to join inferior vena cava. As inferior vena cava drains into the right atrium, the oxygenated and nutrient-rich blood brought by it enters the right atrium. Then it passes into the left atrium through ‘foramen ovale’, thus bypassing the pulmonary circuit (Figs 18.31 and 18.32).

From the left atrium, it enters the left ventricle and traverses the systemic circuit via the ascending aorta, arch of aorta and descending thoracic and descending abdominal aortae. The last mentioned vessel divides into common iliac arteries. Each common iliac artery terminates by dividing into external and internal iliac arteries. Arising from two internal iliac arteries are the two umbilical arteries which in turn pass through the umbilical cord to end in the placenta.

So for bypassing the lungs and for providing oxygen and nutrition to the developing embryo and foetus, the following structures had to be improvised.

- One umbilical vein
- Ductus venosus
- Foramen ovale
- Ductus arteriosus
- Two umbilical arteries.

Flowchart 18.1 shows the details of foetal circulation.

At the time of birth, with the start of breathing process, these structures (a–e) retrogress and gradually the adult form of circulation takes over (Flowchart 18.2).
Changes at birth:
Lungs start functioning.

a. Umbilical vein forms ligamentum teres.
b. Ductus venosus forms ligamentum venosum.
c. Foramen ovale closes.
d. Ductus arteriosus forms ligamentum arteriosum.
Fig. 18.32: Details of foetal circulation. Percentage of oxygen in blood vessels is put in numbers

- Umbilical arteries form medial umbilical ligaments. Placenta is delivered and removed.

**Competency achievement:** The student should be able to: AN 25.4 Describe embryological basis of:

1. **Atrial septal defect:** Normally septum primum fuses with septum seconum to obliterate interatrial foramen. Incomplete fusion of the two septa leads to atrial septal defect.

2. **Ventricular septal defect:** Ventricular septal defect is due to defect in the formation of membranous part of interventricular septum. This septum is formed by right and left bulbar ridges and proliferating posterior endocardial cushion. Improper fusion of these three leads to ventricular septal defect. The membranous part of interventricular septum is of neural crest origin.

3. **Fallot’s tetralogy:** The components of Fallot’s tetralogy are:
   - a. Patent interventricular foramen
   - b. Overriding of the aorta
   - c. Pulmonary stenosis
   - d. Right ventricular hypertrophy
PERICARDIUM AND HEART

**Mnemonics**

*Heart valves* “Try Pulling My Aorta”
- Tricuspid
- Pulmonary
- Mitral
- Aorta
- Atrioventricular valve

"LAB RAT"
- Left atrium: Bicuspid
- Right atrium: Tricuspid

**Lung lobe numbers: Right vs left**
- Tricuspid heart valve and tri-lobed lung both on the right side.
- Bicuspid and bi-lobed lung both on the left side.

**FACTS TO REMEMBER**
- Heart is a pump for pushing blood to the lungs and for rest of the organs of the body. Due to sympathetic stimulation, it is felt thumping against the chest wall.

**Flowchart 18.2: Postnatal circulation**

- Superior vena cava
  - Right atrium
  - Pulmonary trunk
  - Right and left pulmonary arteries
  - Lungs (blood gets oxygenated)
- Left atrium
- Left ventricle
- Aorta
- Whole body except lungs
- Body tissues

- Inferior vena cava
- Venous blood from head, neck, brain and upper limbs
- Venous blood from lower limbs, abdomen and thorax

**CLINICOANATOMICAL PROBLEMS**

**Case 1**
An adult man was stabbed on his upper left side of chest. He was taken to the casualty department of the hospital. The casualty physician noted that the stab wound was in left third intercostal space close to the sternum. Further the patient has engorged veins on the neck and face.
- What is the site of injury?
- Why are the veins of the neck and face engorged?
- What procedure would be done as an emergency measure before taking him to operation theatre?

**Ans:** The injury is in left third intercostal space injuring the pericardium and right ventricle, causing haemopericardium. Veins of the neck and face are engorged as the venae cavae are not able to pour blood in the right atrium. Pericardial tapping is done to take out the blood from the pericardial cavity. It is done as an emergency measure.

**Case 2**
A 40-year-old lady while playing tennis, suddenly fell down, holding onto her chest and left arm due to severe pain.
- Why is the pain in her chest?
- Why is the pain in her left arm?

**Ans:** Tennis is a very strenuous game. The lady fainted as there was more need for the oxygen. Since it could not be supplied, the myocardium got ischaemic which caused visceral pain. The pain is carried by afferents which travel mostly with left side sympathetic nerves to the thoracic one and thoracic 2–5 segments of the spinal cord. Since somatic nerves (T1–T5) also travel to the same segments, the pain is referred to the skin area. T1 supplies the medial side of arm and T2–T5 supply the intercostal spaces.

**Case 3**
A 10-year-old boy had mild cough and fever. The physician could feel the increased rate of his pulse, but could not hear the heartbeat on the left side of his chest. After some thought, the physician was able to feel the heartbeat as well.
3. Write short notes on:
   a. Sinuses of pericardium
   b. Interventricular septum
c. Valves of the heart
d. Comparison of right and left coronary arteries
e. Coronary sinus

- What is mitral stenosis and mitral regurgitation?
- Why is mitral stenosis common after throat infection?
- Which bacteria are responsible for such an incident?
- How is interatrial septum formed?
INTRODUCTION
Superior vena cava brings deoxygenated blood from the head and neck, upper limbs and thorax to the heart. Aorta and pulmonary trunk are the only two exit channels from the heart, developing from a single truncus arteriosus. The two are intimately related to each other.

DISSECTION
Trace superior vena cava from level of first right costal cartilage where it is formed by union of left and right brachiocephalic veins till the third costal cartilage where it opens into right atrium (Fig. 19.1).
Trace the ascending aorta from the vestibule of left ventricle upwards between superior vena cava and pulmonary trunk (Fig. 19.2).
Arch of aorta is seen above the bifurcation of pulmonary trunk.
Cut ligamentum arteriosum as it connects the left pulmonary artery to the arch of aorta.
Trace the left recurrent laryngeal nerve to the medial aspect of arch of aorta.
Lift the side of oesophagus forwards to expose the anterior surface of the descending aorta.
Lift the diaphragm forwards and expose the aorta in the inferior part of the posterior mediastinum.

Competency achievement: The student should be able to:
AN 23.3 Describe and demonstrate origin, course, relations, tributaries and termination of superior vena cava (described below), azygos, hemiazygos and accessory hemiazygos veins (described in Chapter 14). 1

SUPERIOR VENA CAVA
Superior vena cava is a large venous channel which collects blood from the upper half of the body and drains it into the right atrium. It is formed by the union of the right and left brachiocephalic or innominate veins behind the lower border of the first right costal cartilage close to the sternum. Each brachiocephalic vein is formed behind the corresponding sternoclavicular joint by the union of the internal jugular and subclavian veins (Fig. 19.1).

Course
The superior vena cava is about 7 cm long. It begins behind the lower border of the sternal end of the first right costal cartilage, pierces the pericardium opposite the second right costal cartilage, and terminates by opening into the upper part of the right atrium behind the third right costal cartilage (Fig. 19.2). It has no valves.

Relations
1 Anterior
   a. Chest wall
   b. Internal thoracic vessels
   c. Anterior margin of the right lung and pleura
   d. The vessel is covered by pericardium in its lower half (Fig. 19.2).
2 Posterior
   a. Trachea and right vagus (posteromedial to the upper part of the vena cava) (see Fig. 16.2)
   b. Root of right lung posterior to the lower part
3 Medial
   a. Ascending aorta
   b. Brachiocephalic artery
4 Lateral
   a. Right phrenic nerve with accompanying vessels
   b. Right pleura and lung (Fig. 19.5)

Tributaries
1 The azygos vein arches over the root of the right lung and opens into the superior vena cava at the level of the second costal cartilage, just before the latter enters the pericardium.
2 Several small mediastinal and pericardial veins drain into the vena cava.
CLINICAL ANATOMY

- When the superior vena cava is obstructed above the opening of the azygos vein, the venous blood of the upper half of the body is returned through the azygos vein; and the superficial veins are dilated on the chest up to the costal margin (Fig. 19.3). Blood from upper limb is returned through the communicating veins joining the veins around the scapula with the intercostal veins. The latter veins of both sides drain into vena azygos (see Flowchart 14.1).
- When the superior vena cava is obstructed below the opening of the azygos veins, the blood is returned through the inferior vena cava via the femoral vein; and the superior veins are dilated on both the chest and abdomen up to the saphenous opening in the thigh. The superficial vein connecting the lateral thoracic vein with the superficial epigastric vein is known as the thoracoepigastric vein (Fig. 19.4) (see Flowchart 14.2).
- In cases of mediastinal syndrome, the signs of superior vena caval obstruction are the first to appear.

AORTA

The aorta is the great arterial trunk which receives oxygenated blood from the left ventricle and distributes it to all parts of the body. It is studied in thorax in the following three parts:
ASCENDING AORTA

Origin and Course

The ascending aorta arises from the upper end of the left ventricle. It is about 5 cm long and is enclosed in the pericardium (Fig. 19.2). It begins behind the left half of the sternum at the level of the lower border of the third costal cartilage. It runs upwards, forwards and to the right and becomes continuous with the arch of the aorta at the sternal end of the upper border of the second right costal cartilage.

At the root of the aorta, there are three dilatations of the vessel wall, called the aortic sinuses. The sinuses are anterior, left posterior and right posterior.

Relations

Anterior
1. Sternum
2. Right lung and pleura
3. Infundibulum of the right ventricle
4. Root of the pulmonary trunk (Fig. 19.5)
5. Right auricle

Posterior
1. Transverse sinus of pericardium

To the Right
1. Superior vena cava
2. Right atrium

To the Left
1. Pulmonary trunk above
2. Left atrium below

Branches

1. The right coronary artery arises from anterior aortic sinus.
2. Left coronary artery arises from the left posterior aortic sinus.

Competency achievement: The student should be able to:

AN 25.5 Describe developmental basis of congenital anomalies, transposition of great vessels, dextrocardia, patent ductus arteriosus and coarctation of aorta.2
AN 23.4 Mention the extent, branches and relations of arch of aorta and descending thoracic aorta.3

ARCH OF AORTA

Arch of the aorta is the continuation of the ascending aorta. It is situated in the superior mediastinum behind the lower half of the manubrium sterni.
Course

1. It begins behind the upper border of the second right sternochondral joint (see Figs 17.2 and 17.4).
2. It runs upwards, backwards and to the left across the left side of the bifurcation of trachea. Then it passes downwards behind the left bronchus and on the left side of the body of the fourth thoracic vertebra. It thus arches over the root of the left lung.
3. It ends at the lower border of the body of the fourth thoracic vertebra by becoming continuous with the descending aorta.

Thus the beginning and the end of arch of aorta are at the same level, although it begins anteriorly and ends posteriorly.

Relations

Anteriorly and to the Left

1. Four nerves from before backwards:
   a. Left phrenic
   b. Lower cervical cardiac branch of the left vagus
   c. Superior cervical cardiac branch of left sympathetic chain.
   d. Left vagus (Fig. 19.6).
2. Left superior intercostal vein, deep to the phrenic nerve and superficial to the vagus nerve
3. Left pleura and lung
4. Remains of thymus
**Posteriorly and to the Right**
1. Trachea, with the deep cardiac plexus and the tracheobronchial lymph nodes
2. Oesophagus
3. Left recurrent laryngeal nerve
4. Thoracic duct
5. Vertebral column

**Superior**
1. Three branches of the arch of the aorta:
   a. Brachiocephalic
   b. Left common carotid
   c. Left subclavian arteries (Fig. 19.7)
2. All three arteries are crossed close to their origin by the left brachiocephalic vein.

**Inferior**
1. Bifurcation of the pulmonary trunk (Fig. 19.2).
2. Left bronchus
3. Ligamentum arteriosum with superficial cardiac plexus on it.
4. Left recurrent laryngeal nerve.

**Branches**
1. Brachiocephalic artery which divides into the right common carotid and right subclavian arteries (Fig. 19.2).
2. Left common carotid artery
3. Left subclavian artery

**DESCENDING THORACIC AORTA**
Descending thoracic aorta is the continuation of the arch of the aorta. It lies in the posterior mediastinum (see Fig. 17.4). It continues as abdominal aorta which ends by dividing into right and left common iliac arteries.

**Course**
1. It begins on the left side of the lower border of the body of the fourth thoracic vertebra.

---

**Figs 19.6:** (a) CT scan, and (b) transverse section of the thorax passing through the fourth thoracic vertebra
It descends with an inclination to the right and terminates at the lower border of the twelfth thoracic vertebra.

**Relations**

**Anterior**
1. Root of left lung
2. Pericardium and heart
3. Oesophagus in the lower part
4. Diaphragm

**Posterior**
1. Vertebral column
2. Hemiazygos veins

**To the Right Side**
1. Oesophagus in the upper part
2. Azygos vein
3. Thoracic duct (Fig. 19.5)
4. Right lung and pleura

**To the Left Side**
Left lung and pleura

**Branches**
1. Nine posterior intercostal arteries on each side for the third to eleventh intercostal spaces (Fig. 19.8).
2. The subcostal artery on each side (see Fig. 14.8).
3. Two left bronchial arteries. The right bronchial artery arises from the third right posterior intercostal artery.

---

**Figs 19.7a and b:** (a) CT scan and (b) transverse section of thorax passing through the third thoracic vertebra
4. Oesophageal branches, supplying the middle one-third of the oesophagus.
5. Pericardial branches, to the posterior surface of the pericardium.
6. Mediastinal branches, to lymph nodes and areolar tissue of the posterior mediastinum.
7. Superior phrenic arteries to the posterior part of the superior surface of the diaphragm. Branches of these arteries anastomose with those of the musculophrenic and pericardiophrenic arteries.

**Competency achievement:** The student should be able to:

AN 24.4 Identify phrenic nerve and describe its formation and distribution.

**PHRENIC NERVE**

Phrenic nerve arising from (C3–C5) cervical nerves is a mixed nerve carrying motor fibres to the diaphragm and sensory fibres from mediastinal pleura, pericardium and part of peritoneum. Phrenic nerves of two sides are compared as follows:

**Right phrenic nerve:** Right phrenic nerve is shorter, vertical and deeply placed (see Fig 16.2). It crosses 2nd part of right subclavian artery. It runs along right side of venous system (Fig. 19.6) and passes through vena caval opening of the diaphragm (see Fig. 12.16).

**Left phrenic nerve:** Left phrenic nerve is longer, oblique and not deeply placed (see Fig. 16.3). It crosses 1st part of left subclavian artery. It runs along left side of arterial system and pierces the left cupola of the diaphragm.

**CLINICAL ANATOMY**

- **Aortic knuckle:** In posteroanterior view of radiographs of the chest, the arch of the aorta is seen as a projection beyond the left margin of the mediastinal shadow. The projection is called the aortic knuckle. It becomes prominent in old age (see Fig. 21.12).
- **Coarctation of the aorta:** is a localised narrowing of the aorta opposite to or just beyond the attachment of the ductus arteriosus. An extensive collateral circulation develops between the branches of the subclavian arteries and those of the descending aorta. These include the anastomoses between the anterior and posterior intercostal arteries. These arteries enlarge greatly and produce a characteristic notching on the ribs (Figs 19.9a and b).
- **Ductus arteriosus, ligamentum arteriosum and patent ductus arteriosus:** During foetal life, the ductus arteriosus (Fig. 19.10) is a short wide channel connecting the beginning of the left pulmonary artery with the arch of the aorta immediately distal to the origin of the left subclavian artery. It conducts most of the blood from the right ventricle.
into the aorta, thus short circuiting the lungs. After birth, it is closed functionally within about a week and anatomically within about eight weeks. The remnants of the ductus form a fibrous band called the ligamentum arteriosum. The left recurrent laryngeal nerve hooks around the ligamentum arteriosum.

The ductus may remain patent after birth. The condition is called patent ductus arteriosus and may cause serious problems. The condition can be surgically treated.

- **Aortic arch aneurysm** is a localised dilatation of the aorta which may press upon the left recurrent laryngeal nerve leading to paralysis of left vocal cord and hoarseness. It may also press upon the surrounding structures and cause the mediastinal syndrome (Fig. 19.11), i.e. dyspnoea, dysphagia, dysphonia, etc.

### PULMONARY TRUNK

The wide pulmonary trunk starts from the summit of infundibulum of right ventricle. Both the ascending aorta and pulmonary trunk are enclosed in a common sleeve of serous pericardium, in front of transverse sinus of pericardium. Pulmonary trunk carrying deoxygenated blood, overlies the beginning of ascending aorta. It courses to the left and divides into right and left pulmonary arteries under the concavity of aortic arch at the level of sternal angle (Figs 19.2 and 19.5).

The right pulmonary artery courses to the right behind ascending aorta, and superior vena cava and anterior to oesophagus to become part of the root of the lung. It gives off its first branch to the upper lobe before entering the hilum. Within the lung, the artery descends posterolateral to the main bronchus and divides like the bronchi into lobar and segmental arteries.

The left pulmonary artery passes to the left anterior to descending thoracic aorta to become part of the root of the left lung. At its beginning, it is connected to the inferior aspect of arch of aorta by ligamentum arteriosus, a remnant of ductus arteriosus. Rest of the course is same as of the right branch.

**Competency achievement:** The student should be able to:

AN 25.6 Mention development of aortic arch arteries, SVC, IVC and coronary sinus.⁵

---

**Fig. 19.10: Patent ductus arteriosus**

**Fig. 19.11: Aortic aneurysm**

---
DEVELOPMENT OF ARTERIES (Fig. 19.12)

**Brachiocephalic artery**: Right aortic sac

**Right subclavian artery**: Proximal part from the right 4th aortic arch artery and remaining part from right 7th cervical intersegmental artery.

**Left subclavian artery**: Only left 7th cervical intersegmental artery.

**Common carotid**: Third aortic arch, distal to the external carotid bud and original dorsal aorta cranial to the attachment of third aortic arch.

**External carotid artery**: Develop as sprout from the third aortic arch.

**Pulmonary trunk**: Part of truncus arteriosus.

**Arch of aorta**: Left aortic sac, Left 4th aortic arch, Left dorsal aorta.

Relation to recurrent laryngeal nerve. Recurrent laryngeal is given off from vagi in relation to distal part of 6th arch artery. Since this distal part forms ligamentum arteriosum on left side only, the recurrent laryngeal nerve hooks around this ligamentum in thorax to reach tracheo-oesophageal groove.

On the right side, there is no ligamentum arteriosum. The recurrent laryngeal nerve slips upwards in the neck and hooks around the right subclavian artery to reach the tracheo-oesophageal groove.

**DEVELOPMENT OF SUPERIOR VENA CAVA**

Upper half of superior vena cava (extrapericardial) develops from caudal part of right anterior cardinal vein.

Lower half of superior vena cava (intrapericardial) develops from right common cardinal vein.

**Coronary Sinus**

Coronary sinus is a remnant of left horn of sinus venosus. Great, middle and anterior cardiac veins drain into this sinus.

---

**Mnemonics**

**Thoracic cage: Relations to the important venous structures**

Behind **sternoclavicular** joints: The brachiocephalic veins begin.

Behind the **1st costal cartilage** on the right: The superior vena cava begins.

Behind the **2nd costal cartilage** on the right: The azygos vein ends.

Behind the **3rd costal cartilage** on the right: The superior vena cava ends.

**Arch of Aorta**

“Know your ABC’S”

Aortic arch gives rise to:

- Brachiocephalic trunk
- Left Common Carotid
- Left Subclavian

**Lung Lobe numbers: Right versus left**

Tricuspid heart valve and tri-lobed lung both on the right side.

Bicuspid heart valve and bi-lobed lung both on the left side.
FACTS TO REMEMBER

- Superior vena cava is the second largest vein of the body.
- Vena azygos brings the venous blood from the posterior parts of thoracic and abdominal wall.
- Aorta is the largest elastic artery of the body. It takes oxygenated blood to all parts of the body except the lungs.
- There is a gradual transition from its elastic nature to muscular nature of its branches.
- Pulmonary trunk arises from the right ventricle. It soon divides into right and left pulmonary arteries which carry deoxygenated blood from right ventricle to the lungs for oxygenation.
- Pulmonary trunk and ascending aorta develop from a common source, the truncus arteriosus.
- There is triple relationship between these two vessels:
  - Close to heart, pulmonary trunk lies anterior to ascending aorta.
  - At upper border of heart, pulmonary trunk lies to the left of ascending aorta (Fig. 19.2).
  - A little above this, the right pulmonary artery lies posterior to the ascending aorta.

CLINICOANATOMICAL PROBLEM

A teenage girl was complaining of breathlessness. The physician heard a ‘machine-like murmur’ during auscultation on the second left intercostal space, close to the margin of sternum. There was continuous thrill on the same site. On getting radiographs of chest and angiocardiography, a diagnosis of patent ductus arteriosus was made.

- What is the ‘machine-like’ murmur?
- How can the shunting of blood be prevented?
- Describe briefly the function of ductus arteriosus during prenatal life. When does it close?

Ans: The ductus arteriosus is a patent channel during fetal life for conducting the blood from left pulmonary artery to arch of aorta beyond the origin of left subclavian artery. The ductus carries blood from right ventricle to descending thoracic aorta. This is necessary as lungs are not functioning. After birth, with the functioning of lungs, ductus arteriosus obliterates and becomes ligamentum arteriosus. If this does not take place (as it occurs in one out of 3000 births), there is back flow of blood from aorta into pulmonary artery giving rise to ‘machine-like’ murmur. The treatment is surgical.

From Medical Council of India, Competency based Undergraduate Curriculum for the Indian Medical Graduate, 2018;1:44–80.
1. Name the parts of aorta. Describe arch of aorta under the following heading:
   a. Beginning
   b. Course
   c. Relations
   d. Branches

2. Describe the foetal circulation

3. Write short notes on:
   a. Branches of descending thoracic aorta
   b. Patent ductus arteriosus
   c. Obstruction of superior vena cava

---

**Multiple Choice Questions**

1. Branches of arch of aorta are all, *except*:
   a. Brachiocephalic trunk
   b. Left common carotid
   c. Left subclavian
   d. Vertebral

2. How many pairs of posterior intercostal arteries arise from descending thoracic aorta?
   a. Nine
   b. Eleven
   c. Ten
   d. Twelve

3. Aortic aneurysm may cause following symptoms:
   a. Dyspnoea
   b. Dysphagia
   c. Dysphonia
   d. All of the above

4. Posterior relations of ascending aorta are all, *except*:
   a. Transverse sinus of pericardium
   b. Right atrium

INTRODUCTION

Trachea or windpipe is the patent tube for passage of air to and from the lungs. In contrast, oesophagus lying behind the trachea opens only while drinking or eating. Thoracic duct brings the lymph from major parts of the body to the root of the neck.

Competency achievement: The student should be able to:

AN 24.6 Describe the extent, length, relations, blood supply, lymphatic drainage and nerve supply of trachea.

TRACHEA

The trachea (Latin air vessel) is a wide tube lying more or less in the midline, in the lower part of the neck and in the superior mediastinum. Its upper end is continuous with the lower end of the larynx. The trachea in the neck is covered by the isthmus of the thyroid gland and acts as a shield for trachea. At its lower end, the trachea ends by dividing into the right and left principal bronchi (Fig. 20.1).

The trachea is 10 to 15 cm in length. Its external diameter measures about 2 cm in males and about 1.5 cm in females. The lumen is smaller in the living than in the cadaver. It is about 3 mm at one year of age. During childhood, it corresponds to the age in years, with a maximum of about 12 mm in adults, i.e. it increases 1 mm per year up to 12 years.

The upper end of the trachea lies at the lower border of the cricoid cartilage, opposite the sixth cervical vertebra. In the cadaver, its bifurcated lower end lies at the lower border of the fourth thoracic vertebra, corresponding in front to the sternal angle. However, in living subjects, in the erect posture, the bifurcation lies at the lower border of the sixth thoracic vertebra and descends still further during inspiration.

Over most of its length, the trachea lies in the median plane, but near the lower end, it deviates slightly to the right. As it runs downwards, the trachea passes slightly backwards following the curvature of the spine.

Relations of the Thoracic Part

Anteriorly

1. Manubrium sterni
2. Sternothyroid muscles
3. Remains of the thymus
4. Left brachiocephalic and inferior thyroid veins
5 Aortic arch, brachiocephalic and left common carotid arteries
6 Deep cardiac plexus (see Fig. 19.6)
7 Some lymph nodes

**Posteriorly**
1 Oesophagus
2 Vertebral column

**On the Right Side**
1 Right lung and pleura
2 Right vagus
3 Azygos vein (Fig. 20.2)

**On the Left Side**
1 Arch of aorta, left common carotid and left subclavian arteries
2 Left recurrent laryngeal nerve (Fig. 20.3)

**Structure**
The trachea has a fibroelastic wall supported by a cartilaginous skeleton formed by C-shaped rings. The rings are about 16 to 20 in number and make the tube convex anterolaterally. Posteriorly, there is a gap which is closed by a fibroelastic membrane and contains transversely arranged smooth muscle known as the trachealis. The lumen is lined by ciliated columnar epithelium and contains many mucous and serous glands.

**Arterial Supply:** Inferior thyroid arteries.
**Venous drainage:** Into the left brachiocephalic vein.
**Lymphatic drainage:** To the pretracheal and paratracheal nodes.

**Nerve Supply**
1 **Parasympathetic:** Nerves through vagi and recurrent laryngeal nerves. It is:
   a. Sensory and secretomotor to the mucous membrane.
   b. Motor to the trachealis muscle.
2 **Sympathetic:** Fibres from the middle cervical ganglion reach it along the inferior thyroid arteries and are vasomotor.

**Development**
Development of trachea is described in respiratory system (see Chapter 16).

**Competency achievement:** The student should be able to:

AN 25.1 Identify, draw and label a slide of trachea and lung.

**HISTOLOGY OF TRACHEA**
Trachea is a thin-walled flexible tube. The trachea is lined by pseudostratified ciliated columnar epithelium with interspersed goblet cells resting on a basement membrane. The lamina propria consists of elastic fibres, lymphocytes both segregated and aggregated and short ducts of the glands (Fig. 20.4). The submucosa which contains both mucous and serous acini that keep the epithelium moist. The most characteristic feature of
323

TRACHEA, OESOPHAGUS AND THORACIC DUCT

The trachea is its supporting framework of 16–20 C-shaped hyaline cartilages that encircle it on its ventral and lateral aspects. The cartilage is covered by perichondrium on all sides which separates it from the neighbouring structures. The outermost layer is the adventitia which contains blood vessels and nerves.

CLINICAL ANATOMY

- In radiographs, the trachea is seen as a vertical translucent shadow due to the contained air in front of the cervicothoracic spine (see Fig. 21.12).
- Clinically, the trachea is palpated in the suprasternal notch. Normally, it is median in position. Shift of the trachea to any side indicates a mediastinal shift.
- During swallowing when the larynx is elevated, the trachea elongates by stretching because the tracheal bifurcation is not permitted to move by the aortic arch. Any downward pull due to sudden and forced inspiration, or aortic aneurysm will produce the physical sign known as ‘tracheal tug’.
- Tracheostomy: It is a surgical procedure which allows air to enter directly into trachea. It is done in cases of blockage of air pathway in nose or larynx.
- As the tracheal rings are incomplete posteriorly, the oesophagus can dilate during swallowing. This also allows the diameter of the trachea to be controlled by the trachealis muscle. This muscle narrows the caliber of the tube, compressing the contained air, if the vocal cords are closed. This increases the explosive force of the blast of compressed air, as occurs in coughing and sneezing.

Mucus secretions help in trapping inhaled foreign particles, and the soiled mucus is then expelled by coughing. The cilia of the mucous membrane beat upwards, pushing the mucus towards the pharynx.

- The trachea may get compressed by pathological enlargements of the thyroid, the thymus, lymph nodes and the aortic arch. This causes dyspnoea, irritative cough, and often a husky voice.

Competency achievement: The student should be able to:

AN 23.1 Describe and demonstrate the external appearance, relations, blood supply, nerve supply, lymphatic drainage and applied anatomy of oesophagus.

OESOPHAGUS

Features

The oesophagus is a narrow muscular tube, forming the food passage between the pharynx and stomach. It extends from the lower part of the neck to the upper part of the abdomen (Fig. 20.2). The oesophagus is about 25 cm long. The tube is flattened anteroposteriorly and the lumen is kept collapsed; it dilates only during the passage of the food bolus. The pharyngo-oesophageal junction is the narrowest part of the alimentary canal except for the vermiform appendix.

The oesophagus begins in the neck at the lower border of the cricoid cartilage, where it is continuous with the lower end of the pharynx.

It descends in front of the vertebral column through the superior and posterior parts of the mediastinum, and pierces the diaphragm at the level of tenth thoracic vertebra. It ends by opening into the stomach at its cardiac end at the level of eleventh thoracic vertebra.

DISSECTION

Remove the posterior surface of the parietal pericardium between the right and left pulmonary veins. This uncovers the anterior surface of the oesophagus in the posterior mediastinum.

Find the azygos vein and its tributaries on the vertebral column to the right of the oesophagus. Find and follow the thoracic duct on the left of azygos vein.

Identify the sternal, sternocostal, interchondral and costochondral joints on the anterior aspect of chest wall which was reflected downwards.

Expose the ligaments which unite the heads of the ribs to the vertebral bodies and intervertebral discs.

Curvatures

In general, the oesophagus is vertical, but shows slight curvatures in the following directions. There are two
side-to-side curvatures, both towards the left (see Fig. 17.4). One is at the root of the neck and the other near the lower end. It also has anteroposterior curvatures that correspond to the curvatures of the cervicothoracic spine.

**Constrictions**

Normally, the oesophagus shows four constrictions. These are seen as indentations.

1. At its beginning, 15 cm/6-inch from the incisor teeth, where it is crossed by cricopharyngeus muscle.
2. Where it is crossed by the aortic arch, 22.5 cm/9-inch from the incisor teeth.
3. Where it is crossed by the left bronchus, 27.5 cm/11-inch from the incisor teeth (Fig. 20.9).
4. Where it pierces the diaphragm 37.5 cm/15-inch from the incisor teeth.

The distances from the incisor teeth are important in passing instruments like endoscope into the oesophagus.

For the sake of convenience, the relations of the oesophagus may be studied in three parts—cervical, thoracic and abdominal. The relations of the cervical part are described in *BD Chaurasia’s Human Anatomy*, Volume 3, and those of the abdominal part in Volume 2.

**Relations of the Thoracic Part of the Oesophagus**

**Anteriorly**

1. Trachea
2. Right pulmonary artery
3. Left bronchus
4. Pericardium with left atrium
5. The diaphragm (Figs 20.2 and 20.3).

**Posteriorly**

1. Vertebral column
2. Right posterior intercostal arteries
3. Thoracic duct
4. Azygos vein with the terminal parts of the hemi-azygos veins
5. Thoracic aorta
6. Right pleural recess
7. Diaphragm (Fig. 20.5)

**To the Right**

1. Right lung and pleura
2. Azygos vein
3. The right vagus (Figs 20.6a to c)

**To the Left**

1. Aortic arch
2. Left subclavian artery
3. Thoracic duct
4. Left lung and pleura
5. Left recurrent laryngeal nerve, all in the superior mediastinum (see Figs 19.5 and 19.6)

In the posterior mediastinum, it is related to:

1. The descending thoracic aorta
2. The left lung and mediastinal pleura (see Fig. 16.3)

**Arterial Supply**

1. The cervical part including the segment up to the arch of aorta is supplied by the inferior thyroid arteries.
2. The thoracic part is supplied by the oesophageal branches of the aorta.
3. The abdominal part is supplied by the oesophageal branches of the left gastric artery.

---

**Fig. 20.5:** Structures in the posterior mediastinum seen after removal of the heart and pericardium
Venous Drainage
Blood from the upper part of the oesophagus drains into the brachiocephalic veins; from the middle part it goes to the azygos veins; and from the lower end it goes to the left gastric vein and vena azygos via hemiazygos vein. The lower end of the oesophagus is one of the sites of portosystemic anastomoses.

Lymphatic Drainage
The cervical part drains to the deep cervical nodes; the thoracic part to the posterior mediastinal nodes; and the abdominal part to the left gastric nodes.

Nerve Supply
1 Parasympathetic nerves: The upper half of the oesophagus is supplied by the recurrent laryngeal nerves, and the lower half by the oesophageal plexus formed mainly by the two vagi. Parasympathetic nerves are sensory, motor and secretomotor to the oesophagus.

2 Sympathetic nerves: For upper half of oesophagus, the fibres come from middle cervical ganglion and run with inferior thyroid arteries. For lower half, the fibres come directly from upper four thoracic ganglia, to form oesophageal plexus before supplying the oesophagus. Sympathetic nerves are vasomotor.

The oesophageal plexus is formed mainly by the parasympathetic through vagi but sympathetic fibres are also present. Towards the lower end of the oesophagus, the vagal fibres form the anterior and posterior gastric nerves which enter the abdomen through the oesophageal opening of the diaphragm.

Development
Described in Chapter 19 of BD Chaurasia’s Human Anatomy, Volume 2.

HISTOLOGY OF OESOPHAGUS
The oesophagus is a muscular tube that rapidly propels the food from pharynx into the stomach. It is about 25 cm long. The mucous membrane is thrown into longitudinal folds when empty. The epithelium is stratified squamous non-keratinised in character and protective in function. The lamina propria sends papillae into the epithelium. The muscularis mucosae is indistinct at the beginning of oesophagus, but becomes distinct lower down (Fig. 20.7). The
submucosa contains oesophageal glands. These are mucus secreting glands with acini which are round or oval in shape. The muscularis externa has striated muscle fibres in upper third, mixed, i.e. both striated and smooth muscle fibres in the middle third and smooth muscle fibres in the lower third of oesophagus.

The outermost layer is the adventitia which is made up of loose connective tissue with capillaries and nerves.

CLINICAL ANATOMY

- In portal hypertension, the communications between the portal and systemic veins draining the lower end of the oesophagus dilate. These dilatations are called oesophageal varices. Rupture of these varices can cause serious haematemesisis or vomiting of blood. The oesophageal varices can be visualised radiographically by barium swallow; they produce worm-like shadows (Fig. 20.8).

- Left atrial enlargement as in mitral stenosis can also be visualised by barium swallow. The enlarged atrium causes a shallow depression on the front of the oesophagus. Barium swallow also helps in the diagnosis of oesophageal strictures, carcinoma and achalasia cardia.

- The normal indentations on the oesophagus should be kept in mind during oesophagoscopy (Fig. 20.9).

- The lower end of the oesophagus is normally kept closed. It is opened by the stimulus of a food bolus. In case of neuromuscular incoordination, the lower end of the oesophagus fails to dilate with the arrival of food which, therefore, accumulates in the oesophagus. This condition of neuromuscular incoordination characterised by inability of the oesophagus to dilate is known as ‘achalasia cardia’. It may be due to congenital absence of nerve cells in wall of oesophagus.

- Improper separation of the trachea from the oesophagus during development gives rise to tracheo-oesophageal fistula (Fig. 20.10).

- Compression of the oesophagus in cases of mediastinal syndrome causes dysphagia or difficulty in swallowing.
Competency achievement: The student should be able to:

**AN 23.7** Mention the extent, relations and applied anatomy of right lymphatic duct.5

## THORACIC DUCT

### Features

The thoracic duct is the largest lymphatic vessel in the body. It extends from the upper part of the abdomen to the lower part of the neck, crossing the posterior and superior parts of the mediastinum. It is about 45 cm/18 inch long. It has a beaded appearance because of the presence of many valves in its lumen (Fig. 20.11).

### Course

The thoracic duct begins as a continuation of the upper end of the cisterna chyli near the lower border of the twelfth thoracic vertebra and enters the thorax through the aortic opening of the diaphragm (see Fig. 12.16).

It then ascends through the posterior mediastinum from level of twelfth thoracic vertebra to fifth thoracic vertebra, where it crosses from the right side to the left side. Then it courses through the superior mediastinum along the left edge of the oesophagus and reaches the neck.

In the neck, it arches laterally at the level of the transverse process of seventh cervical vertebra. Finally it descends in front of the first part of the left subclavian artery and ends by opening into the angle of junction between the left subclavian and left internal jugular veins (Fig. 20.12).

### Relations

**At the Aortic Opening of the Diaphragm**

**Anteriorly:** Diaphragm

![Fig. 20.11: The course of the thoracic duct](image)

**Fig. 20.12: The tributaries of the thoracic duct**
Posteriorly: Vertebral column
To the right: Azygos vein
To the left: Aorta (see Fig. 12.16)

In the Posterior Mediastinum
Anteriorly
1 Diaphragm (Fig. 20.6c)
2 Oesophagus
3 Right pleural recess

Posteriorly
1 Vertebral column
2 Right posterior intercostal arteries
3 Terminal parts of the hemiazygos veins
To the right: Azygos vein
To the left: Descending thoracic aorta (Fig. 20.6c)

In the Superior Mediastinum
Anteriorly
1 Arch of aorta
2 The origin of the left subclavian artery (Fig. 20.6a)
Posteriorly: Vertebral column
To the right: Oesophagus
To the left: Pleura

In the Neck
The thoracic duct forms an arch rising about 3–4 cm above the clavicle. The arch has the following relations.
Anteriorly
1 Left common carotid artery
2 Left vagus
3 Left internal jugular vein

Posteriorly
1 Vertebral artery and vein.
2 Sympathetic trunk
3 Thyrocerical trunk and its branches
4 Left phrenic nerve
5 Medial border of the scalenus anterior
6 Prevertebral fascia covering all the structures mentioned
7 The first part of the left subclavian artery

Tributaries
The thoracic duct receives lymph from, roughly, both halves of the body below the diaphragm and the left half above the diaphragm (Fig. 20.12).

In the thorax, the thoracic duct receives lymph vessels from the posterior mediastinal nodes and from small intercostal nodes. At the root of the neck, efferent vessels of the nodes in the neck form the left jugular trunk, and those from nodes in the axilla form the left subclavian trunk. These trunks end in the thoracic duct. The left bronchomediastinal trunk drains lymph from the left half of the thorax and ends in the thoracic duct.

On the right side, there is right lymphatic duct into which right bronchomediastinal, right jugular and right subclavian lymph trunks drain. The right lymphatic trunk ends in the right brachiocephalic vein at the junction of right subclavian and right internal jugular veins.

FACTS TO REMEMBER
• Trachea contains C-shaped hyaline cartilaginous rings which are deficient posteriorly, so that the oesophagus situated behind the trachea is not compressed by trachea.
• Trachea begins at sixth cervical vertebra and ends at thoracic 4 (in expiration) by dividing into two principal bronchi. Trachea is always patent.
• Oesophagus is 25 cm long, like duodenum and ureter. Its maximum part about 20 cm/8-inch lie in thoracic cavity.
• There is no digestive activity in the oesophagus. Lower part of oesophagus is a site of portocaval anastomoses.
• Thoracic duct drains lymph from both lower limbs, abdominal cavity, left side of thorax, left upper limb and left side of head and neck.

CLINICOANATOMICAL PROBLEM
A young lady during her midpregnancy period complained of rapid breathing and difficulty in swallowing. She also gave a history of sore throat with pains in her joints during childhood.

What is the likely diagnosis?
What is the explanation for her symptoms?
Ans: The diagnosis most likely is rheumatic heart. It occurs due to streptococcal infection in the throat. Its toxins affect the mitral valve of the heart and kidney as well. In this case, her mitral valve got affected, leading to mitral stenosis which causes left atrial enlargement due to its incomplete emptying into the left ventricle.

The enlarged left atrium presses on the oesophagus, as it passes behind the heart and pericardium. So the patient complains of dysphagia. A simple barium swallow can show the enlarged left atrium causing pressure on the oesophagus.

As enough blood is not reaching the lungs, there is anoxia in the body, leading to rapid breathing.

FURTHER READING
1. Indentations in the oesophagus are caused by all, except:
   a. Aortic arch  b. Left bronchus  c. Left atrium  d. Left ventricle
2. In mitral stenosis, barium swallow is done to see compression of oesophagus due to enlargement of:
   a. Right atrium  b. Left atrium  c. Left ventricle  d. Right ventricle
3. Oesophageal varices are seen in which part of oesophagus?
   a. Upper end  b. Middle region  c. Lower end  d. Whole of oesophagus
4. Right side relations of thoracic part of oesophagus are all, except:
   a. Right lung and pleura  b. Azygos vein  c. Right vagus  d. Left vagus

**Answers**
1. d  2. b  3. c  4. d

**VIVA VOCE**
- What is extent of trachea in supine position?
- What is tracheostomy? Where is it done?
- What type of cartilage is present in trachea and bronchi?
- Name the sites of anatomical constrictions in the course of oesophagus.
- Where does thoracic duct start?
- Name the tributaries of thoracic duct.
- Name the tributaries of right lymphatic duct.
INTRODUCTION
Surface marking is the projection of deeper structures on the surface of body.

SURFACE MARKING
The bony and soft tissue surface landmarks have been described in Chapter 12.

The surface marking of important structures is described here.

- Parietal pleura (Fig. 21.1)
- Lungs (Figs 21.2 to 21.4)
- Heart (Fig. 21.5)
- Cardiac valves and ascultatory areas (Fig. 21.6)

Competency achievement: The student should be able to:

AN 25.9 Demonstrate surface marking of lines of pleural reflection, lung borders and fissures, trachea, heart borders, apex beat and surface projection of valves of heart.¹

Surface Marking of Parietal Pleura

The cervical pleura is represented by a curved line forming a dome over the medial one-third of the clavicle with a height of about 2.5 cm above the clavicle. Pleura lies in the root of neck on both sides (points 1 and I) (Fig. 21.1).

The anterior margin, the costomediastinal line of pleural reflection is as follows: On the right side, it extends from the sternoclavicular joint downwards and medially to the midpoint of the sternal angle (point 2). From here it continues vertically downwards to the midpoint of the xiphisternal joint crosses to right of xiphicostal angle (point 3). On the left side, the line follows the same course up to the level of the fourth costal cartilage. It then arches outwards and descends along the sternal margin up to the sixth costal cartilage (points I–IV).

The inferior margin, or the costodiaphragmatic line of pleural reflection (same on both sides) passes laterally
SURFACE MARKING AND RADIOLOGICAL ANATOMY OF THORAX

331

Fig. 21.2: Parietal (black) and visceral pleurae and lung (pink) from the lateral aspect. Costodiaphragmatic recess is seen.

from the lower limit of its anterior margin, so that it crosses the eighth rib in the midclavicular line (Fig. 21.2),
the tenth rib in the midaxillary line, and the twelfth rib at the lateral border of the sacrospinalis muscle
(Fig. 21.3). Further it passes horizontally a little below the twelfth rib to the lower border of the twelfth thoracic
vertebra, 2 cm lateral to the upper border of the twelfth thoracic spine (Fig. 21.3).

Thus the pleurae descend below the costal margin at three places, at the right xiphicostal angle, and at
the right and left costovertbral angles below the twelfth rib behind the upper poles of the kidneys. The
latter fact is of surgical importance in exposure of the kidney. The pleura may be damaged at these sites
(Fig. 21.1).

The posterior margins of the pleura pass from a point 2 cm lateral to the twelfth thoracic spine to a point 2 cm
lateral to the seventh cervical spine. The costal pleura becomes the mediastinal pleura along this line.

- Points 4 and 5 in Fig. 21.2—right side
- Points 6 and 7 in Fig. 21.3—right side
- Points V and VI in Fig. 21.1—left side
- Points VII and VIII in Fig. 21.3—left side

Surface Making of the Lungs

The apex of the lung coincides with the cervical pleura, and is represented by a line convex upwards rising
2.5 cm above the medial one-third of the clavicle point 1 on right and I on left side (Fig. 21.4).

The anterior border of the right lung corresponds very closely to the anterior margin or costomediastinal line
of the pleura and is obtained by joining:

- Point 2 at the sternoclavicular joint,
- Point 3 in the median plane at the sternal angle,
- Point 4 in the median plane just above the xiphisternal joint.

The anterior border of the left lung corresponds to the anterior margin of the pleura up to the level of the
fourth costal cartilage points II–IV.

In the lower part, it presents a cardiac notch of variable size. From the level of the fourth costal
cartilage, it passes laterally for 3.5 cm from the sternal margin, and then curves downwards and medially to reach the sixth costal cartilage 4 cm from the median plane (points V and VI). In the region of the cardiac notch, the pericardium is covered only by a double layer of pleura. The area of the cardiac notch is dull on percussion and is called the area of superficial cardiac dullness.

The lower border of each lung (same on both the sides) lies two ribs higher than the parietal pleural reflection. It crosses the sixth ribs (points 5 and VI) in the midclavicular line, the eighth rib (points 6 and VII) in the midaxillary line (Fig. 21.4), the tenth rib at the lateral border of the erector spinae, and ends 2 cm lateral to the tenth thoracic spine (Fig. 21.3).

The posterior border coincides with the posterior margin of the pleural reflection except that its lower end lies at the level of the tenth thoracic spine (Fig. 21.3).

The oblique fissure can be drawn on both sides by joining:
- A point 2 cm lateral to the third thoracic spine.
- Another point on the fifth rib in the midaxillary line (Figs 21.2 and 21.4).
- A third point on the sixth costal cartilage 7.5 cm from the median plane.

The horizontal fissure is represented only on right side by a line joining:
- A point on the anterior border of the right lung at the level of the fourth costal cartilage.
- A second point on the fifth rib in the midaxillary line (Fig. 21.2).

Between the visceral and parietal pleurae, the recesses are present. Costodiaphragmatic recesses are present on both sides and are about 4–5 cm deep. Costomediastinal recess is prominent on left side, to left of sternum between 4th and 6th costal cartilages.

**Surface Marking of the Borders of the Heart**
- Point 1 at the lower border of the second left costal cartilage about 1.3 cm from the sternal margin (Fig. 21.5).
• Point 2 at the upper border of the third right costal cartilage 0.8 cm from the sternal margin.
• Point 3 in the right 4th intercostal space 3.8 cm from median plane.
• Point 4 at the lower border of the sixth right costal cartilage 2 cm from the sternal margin.
• Point 5 at the apex of the heart in the left fifth intercostal space 9 cm from the midsternal line.
• Joining of points 1 and 2 forms upper border.
• The right border is marked by a line, slightly convex to the right, joining the points 2, 3 and 4. The maximum convexity is about 3.8 cm from the median plane in the fourth space.
• The inferior border is drawn by joining points 4 and 5.
• The left border is marked by a line, fairly convex to the left, joining the points 1 and 5.

Atrioventricular groove is marked by a line drawn from the sternal end of left 3rd costal cartilage to the sternal end of right sixth costal cartilage.

The area of the chest wall overlying the heart is called the precordium.

Surface Marking of the Cardiac Valves and the Auscultatory Areas

Sound produced by closure of the valves of the heart can be heard using a stethoscope. The sound arising in relation to a particular valve are best heard not directly over the valve, but at areas situated some distance away from the valve in the direction of blood flow through it. These are called auscultatory areas. The position of the valves in relation to the surface of the body, and of the auscultatory areas is given in Table 21.1 and Fig. 21.6.

Arteries

Internal Mammary (Thoracic) Artery

It is marked by joining the following points (Fig. 21.7).

</table>

Pulmonary Trunk

1. First mark the pulmonary valve by a horizontal line 2.5 cm long, mainly along the upper border of the left 3rd costal cartilage and partly over the adjoining part of the sternum (Fig. 21.6).
2. Then mark the pulmonary trunk by two parallel lines 2.5 cm apart from the pulmonary orifice upwards to the left 2nd costal cartilage.

Figure 21.6: Surface projection of the cardiac valves. The position of the auscultatory areas is also shown.

Table 21.1: Surface marking of the cardiac valves and the sites of the auscultatory areas (Fig. 21.6)
Fig. 21.7: The origin, course and terminations of the internal thoracic artery (1st–8th costal cartilages)

**Ascendings Aorta**

1. First mark the aortic orifice by a slightly oblique line 2.5 cm long running downwards and to the right over the left half of the sternum beginning at the level of the lower border of the left 3rd costal cartilage (Fig. 21.6).

2. Then mark the ascending aorta by two parallel lines 2.5 cm apart from the aortic orifice upwards to the right half of the sternal angle (Fig. 21.6).

**Arch of the Aorta**

Arch of the aorta lies behind the lower half of the manubrium sterni. Its upper convex border is marked by a line which begins at the right end of the sternal angle, arches upwards and to the left through the centre of the manubrium, and ends at the sternal end of the left second costal cartilage. Note that the beginning and the end of the arch lie at the same level. When marked on the surface as described above, the arch looks much smaller than it actually is because of foreshortening (Fig. 21.8).

**Descending Thoracic Aorta**

Descending thoracic aorta is marked by two parallel lines 2.5 cm apart, which begin at the sternal end of the left second costal cartilage, pass downwards and medially, and end in the median plane 2.5 cm above the transpyloric plane (Fig. 21.8).

**Brachiocephalic Artery**

Brachiocephalic artery is marked by a broad line extending from the centre of the manubrium to the right sternoclavicular joint (Fig. 21.8).

**Left Common Carotid Artery**

The thoracic part of this artery is marked by a broad line extending from a point a little to the left of the centre of the manubrium to the left sternoclavicular joint.

**Left Subclavian Artery**

The thoracic part of the left subclavian artery is marked by a broad vertical line along the left border of the manubrium a little to the left of the left common carotid artery.

**Veins**

**Superior Vena Cava**

Superior vena cava is marked by two parallel lines 2 cm apart, drawn from the lower border of the right first costal cartilage to the upper border of the right first costal cartilage, overlapping the right margin of the sternum (Fig. 21.9).
**Right Brachiophecalic Vein**

It is marked by two parallel lines 1.5 cm apart, drawn from the medial end of the right clavicle to the lower border of the right first costal cartilage close to the sternum (Fig. 21.9).

**Left Brachiophecalic Vein**

It is marked by two parallel lines 1.5 cm apart, drawn from the medial end of the left clavicle to the lower border of the first right costal cartilage. It crosses the left sternoclavicular joint and the upper half of the manubrium (Fig. 21.9).

**Trachea (Thoracic Part)**

Trachea is marked by two parallel lines 2 cm apart, drawn from the lower border of the cricoid cartilage (2 cm below the thyroid notch) to the manubriosternal angle, inclining slightly to the right (Fig. 21.10).

**Right Bronchus**

Right bronchus is marked by a broad line running downwards and to the right for 2.5 cm from the lower end of the trachea to the sternal end of the right third costal cartilage.

**Left Bronchus**

Left bronchus is marked by a broad line running downwards and to the left for 5 cm from the lower end of the trachea to the left third costal cartilage 4 cm from the median plane (Fig. 21.10).

**Oesophagus**

It is marked by one on each side two parallel lines 2.5 cm apart by joining the following points:
1. Two points (one on each side) 2.5 cm apart at the lower border of the cricoid cartilage across the median plane (Fig. 21.11).
2. Two points (one on each side) 2.5 cm apart at the root of the neck a little to the left of the median plane one on each side.
3. Two points (one on each side) 2.5 cm apart at the sternal angle across the median plane.
4. Two points (one on each side) 2.5 cm apart at the left 7th costal cartilage 2.5 cm from the median plane.

**Thoracic Duct**

It is marked by joining the following points.
1. A point 2 cm above the transpyloric plane slightly to the right of the median plane (Fig. 21.10).
2. A second point 2 cm to right of median plane below manubriosternal angle.
3. A third point across to left side at same level.
4. A fourth point 2.5 cm above the left clavicle 2 cm from the median plane.
5. A fifth point just above the sternal angle 1.3 cm to the left of the median plane.

*Competency achievement: The student should be able to:*  
AN 25.7 Identify structures seen on a plain X-ray chest (PA view).  

The most commonly taken radiographs are described as posteroanterior (PA) views. X-rays travel from posterior to the anterior side. A study of such radiographs gives information about the lungs, the dia-
The bones of the vertebrae are partially visible. Costo-transverse joints are seen on each side. The posterior parts of the ribs are better seen because of the large amounts of calcium contained in them. The ribs get wider and thinner as they pass anteriorly. Costal cartilages are not seen unless these are calcified. The medial borders of the scapulae may overlap the periphery of the lung fields.

Trachea
Trachea is seen as air-filled shadow in the midline of the neck. It lies opposite the lower cervical and upper thoracic vertebrae (Fig. 21.12).

Diaphragm
Diaphragm casts dome-shaped shadows on the two sides. The shadow on the right side is little higher than on the left side. The angles where diaphragm meets the thoracic cage are the costophrenic angles—the right and the left. Under the left costophrenic angle is mostly the gas in the stomach, while under the right angle is the smooth shadow of the liver.

Lungs
The dense shadows are cast by the lung roots due to the presence of the large bronchi, pulmonary vessels, bronchial vessels and lymph nodes. The lungs readily permit the passage of the X-rays and are seen as translucent shadows during full inspiration. Both blood vessels and bronchi are seen as series of shadows radiating from the lung roots. The smaller bronchi are not seen. The lung is divided into three zones—upper zone is from the apex till the second costal cartilage. Middle zone extends from the second to the fourth costal cartilage. It includes the hilar region. Lower zone extends from the fourth costal cartilage till the bases of the lungs.

Mediastinum
Shadow is produced by the superimpositions of structures in the mediastinum. It is chiefly produced by the heart and the vessels entering or leaving the heart. The transverse diameter of heart is half the transverse diameter of the thoracic cage. During inspiration, heart descends down and acquires tubular shape. Right border of the mediastinal shadow is formed from above downwards by right brachiocephalic vein, superior vena cava, right atrium and inferior vena cava. The left border of mediastinal shadow is formed from above downwards by aortic arch (aortic knuckle), left margin of pulmonary trunk, left auricle and left ventricle. The inferior border of the mediastinal shadow blends with the liver and diaphragm.
Competency achievement: The student should be able to:

AN 25.8 Identify and describe in brief a barium swallow.3

Barium Swallow

50% suspension of barium sulphate is to be swallowed 2–3 times with patient standing behind fluoroscopic screen. Barium swallow shows the normal position of oesophagus as it lies posterior to aortic arch, left bronchus and the left atrium of heart (Fig. 21.13). Enlargement of left atrium would show narrow oesophagus.

![Fig. 21.13: Barium swallow](image)

NUMERICALS

- Anteroposterior diameter of inlet of thorax—5 cm.
- Transverse diameter of inlet of thorax—10 cm.
- Suprasternal notch—T2 vertebra.
- Sternal angle—disc between T4 and T5 vertebrae. 2nd costal cartilage articulates with the sternum.
- Xiphisternal joint—T9 vertebra.
- Subcostal angle—between sternal attachments of 7th costal cartilages.
- Vertebra prominece—7th cervical spine.
- Superior angle of scapula—level of T2 spine.
- Root of spine of scapula—level of T3 spine.
- Inferior angle of scapula—level of T7 spine.
- Length of oesophagus—25 cm:
  - Cervical part—4 cm
  - Thoracic part—20 cm
  - Abdominal part—1.25 cm
  - Beginning of oesophagus—C6 vertebra
  - Termination of oesophagus—T11 vertebra
- Beginning of trachea—C6 vertebra:
  - Length of trachea—10–15 cm.
  - Bifurcation of trachea—upper border of T5 vertebra.
  - Length of right principal bronchus—2.5 cm.
  - Length of left principal bronchus—5 cm.

TOMOGRAPHY

Tomography is a radiological technique by which radiograms of selected layers (depths) of the body can be made. Tomography is helpful in locating deeply situated small lesions which are not seen in the usual radiograms.

INTRODUCTION
Appendix 2 at the end of the section on thorax gives a bird’s eye view of the sympathetic component of the autonomic nervous system. The course of the typical and atypical intercostal nerves is described briefly. Arteries of thorax have been tabulated. Clinical terms are also given.

AUTONOMIC NERVOUS SYSTEM
The autonomic nervous system comprises sympathetic and parasympathetic components. Sympathetic component is active during fright, fight or flight. During any of these activities, the pupils dilate, skin gets pale, blood pressure rises, blood vessels of skeletal muscles, heart, and brain dilate. The person is tense and gets tired soon (Fig. A2.1). There is hardly any activity in the digestive tracts due to which the individual does not feel hungry.

Parasympathetic component has the opposite effects of sympathetic component. This component is sympathetic to the digestive tract. In its activity, digestion and metabolism of food occurs. Heart beats normally. Person is relaxed and can do creative work (Fig. A2.2).

Autonomic nervous system is controlled by brainstem and cerebral hemispheres. These include reticular formation of brainstem, thalamic and hypothalamic nuclei, limbic lobe and prefrontal cortex including the ascending and descending tracts interconnecting these regions.

Sympathetic Nervous System
Sympathetic nervous system is the larger of the two components of autonomic nervous system. It consists of two ganglionated trunks, their branches, prevertebral ganglia, plexuses. It supplies all the viscera of thorax, abdomen and pelvis, including the blood vessels of head and neck, brain, limbs, skin and the sweat glands as well as arrector pili muscle of skin of the whole body.

The preganglionic fibres are the axons of neurons situated in the lateral horns of T1–L2 segments of spinal cord. They leave spinal cord through their respective

—Murphy’s Law

Fig. A2.1: Actions of sympathetic system
ventral roots, to pass in their nerve trunks, and beginning of ventral rami via white ramus communicans (wrc). There are 14 white rami communicantes on each side. These fibres can have following alternative routes.

1. They relay in the ganglion of the sympathetic trunks, postganglionic fibres pass via the grey rami communicantes and get distributed to the blood vessels of muscles, skin, sweat glands and to arrector pili muscles (Fig. A2.3).

2. These may pass through the corresponding ganglion and ascend to a ganglion higher before terminating in the above manner.

3. These may pass through the corresponding ganglion and descend to a ganglion lower and then terminate in the above manner.

4. These may synapse in the corresponding ganglia and pass medially to the viscera like heart, lungs, oesophagus.

5. These white rami communicantes (wrc) pass to corresponding ganglia and emerge from these as wrc (unrelayed) in the form of splanchnic nerves to supply abdominal and pelvic viscera after synapsing in the ganglia situated in the abdominal cavity. Some fibres of splanchnic nerves pass express to adrenal medulla.

Sympathetic trunk on either side of the body extends from cervical region to the coccygeal region where both trunks fuse to form a single ganglion impar. Sympathetic trunk has cervical, thoracic, lumbar, sacral and coccygeal parts.

**Thoracic Part of Sympathetic Trunk**

There are usually 11 ganglia on the sympathetic trunk of thoracic part. The first ganglion lies on neck of 1st rib and is usually fused with inferior cervical ganglion and forms stellate ganglion. The lower ones lie on the heads of the ribs. The sympathetic trunk continues with its abdominal part by passing behind the medial arcuate ligament.

The ganglia are connected with the respective spinal nerves via the white ramus communicans (from the spinal nerve to the ganglion) and the grey ramus communicans (from the ganglion to the spinal nerve, i.e. ganglion gives grey).
Branches
1. Grey rami communicantes to all the spinal nerves, i.e. T1–T12. The postganglionic fibres pass along the spinal nerves to supply cutaneous blood vessels, sweat glands and arrector pili muscles.
2. Some white rami communicantes from T1 to T5 ganglia travel up to the cervical part of sympathetic trunk to relay in the three cervical ganglia. Fibres from the lower thoracic ganglia T10–L2 pass down as preganglionic fibres to relay in the lumbar or sacral ganglia.
3. The first five thoracic ganglia give postganglionic fibres to heart, lungs, aorta and oesophagus.
4. Lower eight ganglia give fibres which are preganglionic (unrelayed) for the supply of abdominal viscera. These are called splanchnic (visceral) nerves.

Nerve Supply of Heart
Preganglionic sympathetic neurons are located in lateral horns T1–T5 segments of spinal cord. These fibres pass along the respective ventral roots of thoracic nerves, to synapse with the respective ganglia of the sympathetic trunk. After relay, the postganglionic fibres form thoracic branches which intermingle with the vagal fibres, to form cardiac plexus.

Some fibres from T1 to T5 segments of spinal cord reach their respective ganglia. These fibres then travel up to the cervical part of the sympathetic chain and relay in superior, middle and inferior cervical ganglia. After relay, the postganglionic fibres form the three cervical cardiac nerves. Preganglionic parasympathetic neurons for the supply of heart are situated in the dorsal nucleus of vagus nerve.

Sympathetic activity increases the heart rate. Larger branches of coronary are mainly supplied by sympathetic fibres. It causes vasodilatation of coronary arteries. Impulses of pain travel along sympathetic fibres. These fibres pass mostly through left sympathetic trunk and reach the spinal cord via T1–T5 spinal nerves. Thus the pain may be referred to the area of skin supplied by T1–T5 nerves, i.e. retrosternal, medial side of the upper limbs. Since one is more conscious of impulses coming from skin than the viscera, one feels as if the pain is in the skin. This is the basis of the referred pain.

Smaller branches of coronary artery are supplied by parasympathetic nerves. These nerves are concerned with slowing of the cardiac cycle.

The nerves reach the heart by the following two plexuses.

Superficial Cardiac Plexus
Superficial cardiac plexus is formed by the following:
1. Superior cervical cardiac branch of left sympathetic trunk.
2. Inferior cervical cardiac branch of left vagus nerve.

Deep Cardiac Plexus
Deep cardiac plexus consists of two halves which are interconnected and lie anterior to bifurcation of trachea (Table A2.1).

Branches from the cardiac plexus give extensive branches to pulmonary plexuses, right and left coronary plexuses. Branches from the coronary plexuses supply both the atria and the ventricles. Left ventricle gets richer nerve supply because of its larger size.

Nerve Supply of Lungs
The lungs are supplied from the anterior and posterior pulmonary plexuses. Anterior plexus is an extension of deep cardiac plexus. The posterior part is formed from branches of vagus and T2–T5 sympathetic ganglia. Small ganglia are found on these nerves for the relay of parasympathetic impulses brought via vagus nerve fibres. Parasympathetic system is bronchoconstrictor or motor, whereas sympathetic system is inhibitory. Sympathetic stimulation causes relaxation of smooth

muscles of bronchial tubes or bronchodilator. The pressure of inspired air also causes bronchodilatation.

**TYPICAL INTERCOSTAL NERVE**

Typical intercostal nerve is any of the nerves belonging to 3rd to 6th intercostal spaces.

**Beginning**

Typical thoracic spinal nerve after it has given off dorsal primary ramus or dorsal ramus is called the intercostal nerve. It runs in the intercostal space, i.e. between the lower border of rib above and upper border of rib below (see Fig. 14.3).

**Course**

Typical intercostal nerve enters the posterior part of intercostal space by passing behind the posterior intercostal vessels. So the intercostal nerve lies lowest in the neurovascular bundle. The order from above downwards is vein, artery and nerve (VAN). At first, the bundle runs between posterior intercostal membrane and subcostalis, then between inner intercostal and innermost intercostal and lastly between inner intercostal and sternocostalis muscles (see Fig. 14.4).

At the anterior end of intercostal space, the intercostal nerve passes in front of internal thoracic vessels, pierces internal intercostal muscle and anterior intercostal membrane to continue as anterior cutaneous branch which ends by dividing into medial and lateral cutaneous branches (see Fig. 14.4).

**Branches**

1. Communicating branches to the sympathetic ganglion close to the beginning of ventral ramus. The anterior or ventral ramus contains sympathetic fibres from lateral horn of spinal cord gives off a white ramus communicans to the sympathetic ganglion. These fibres get relayed in the ganglion. Some of these relayed fibres pass via grey ramus communicans to ventral ramus. A few pass backwards in the dorsal ramus and rest pass through the ventral ramus. These sympathetic fibres are sudomotor, pilomotor and vasomotor to the skin and vasodilator to the skeletal vessels (see Fig. 14.3).
2. Before the angle, nerve gives a collateral branch that runs along the upper border of lower rib. This branch supplies intercostal muscles, costal pleura and periosteum of the rib.
3. Lateral cutaneous branch arises along the midaxillary line. It divides into anterior and posterior branches.
4. The nerve keeps giving muscular, periosteal, and branches to the costal pleura during its course.
5. Anterior cutaneous branch is the terminal branch of the nerve. It divides into anterior and posterior branches.

**ATYPICAL INTERCOSTAL NERVES**

The thoracic spinal nerves and their branches which do not follow absolutely thoracic course are designated as atypical intercostal nerves. Thus first and second intercostal nerves are atypical as these two nerves partly supply the upper limb.

The first thoracic nerve entirely joins the brachial plexus as its last rami or root. It gives no contribution to the first intercostal space. That is why the nerve supply of skin of first intercostal space is from the supraclavicular nerves (C3, C4) (see Fig. 3.4).

The second thoracic or second intercostal nerve runs in the second intercostal space. But its lateral cutaneous branch as intercostobrachial nerve is rather big and it supplies skin of the axilla as well. Third to sixth intercostal nerves are typical (see Fig. 7.1).

Also seventh, eighth, ninth, tenth, eleventh intercostal nerves are atypical, as these course partly through thoracic wall and partly through anterolateral abdominal wall. Lastly the twelfth thoracic is known as subcostal nerve. It also passes through the anterolateral abdominal muscles. These nerves supply parietal peritoneum, muscles of the anterolateral abdominal wall and overlying skin.

**ARTERIES**

The arteries of thorax are internal thoracic artery, ascending aorta, arch of aorta, descending thoracic aorta and coronary arteries. These have been described with their origin, course, termination and area of distribution in Tables A2.2 and A2.3.

---

**CLINICAL TERMS**

**Site of pericardial tapping:** Removal of pericardial fluid is done in left 4th or 5th intercostal spaces just to the left of the sternum as pleura deviates exposing the pericardium against the medial part of left 4th and 5th intercostal spaces. Care should be taken to avoid injury to internal thoracic artery lying at a distance of 1 cm from the lateral border of sternum. Needle can also be passed upwards and posteriorly from the left xiphicostal angle to reach the pericardial cavity (see Fig. 18.6).

**Foreign bodies in trachea:** Foreign bodies like pins, coins entering the trachea pass into right bronchus; Right bronchus wider shorter, more vertical and is in line with trachea, so the foreign bodies in the trachea travel down into right bronchus and then into posterior basal segments of the lower lobe of the lung (see Fig. 16.5).

**Site of bone marrow puncture:** The manubrium sterni is the favoured site for bone marrow puncture.

</tr>
</thead>
<tbody>
<tr>
<td>INTERNAL THORACIC Artery</td>
<td>Arises from inferior aspect of 1st part of subclavian artery. Its origin lies 2 cm above the sternal end of the clavicle. It runs downwards, forwards and medially behind the clavicle and behind the 1–6 costal cartilages and 1–5 intercostal spaces to terminate in the 6th intercostal space by dividing into superior epigastric and musculophrenic arteries</td>
<td>It supplies pericardium, thymus, upper six intercostal spaces in their anterior parts, mammary gland, rectus sheath and also 7–9 intercostal spaces. Thus it supplies anterior thoracic and anterior abdominal walls from the clavicle to the umbilicus</td>
</tr>
<tr>
<td>Pericardiacophrenic artery</td>
<td>Branch of internal thoracic artery</td>
<td>Supplies fibrous and parietal layer of serous pericardia and the diaphragm</td>
</tr>
<tr>
<td>Mediastinal arteries</td>
<td>Small branches of internal thoracic artery</td>
<td>Supply thymus and fat in the mediastinum</td>
</tr>
<tr>
<td>Two anterior intercostal arteries</td>
<td>Two arteries, each arises in 1–6 upper intercostal spaces from internal thoracic artery</td>
<td>Supply muscles of the 1–6 intercostal spaces and parietal pleura</td>
</tr>
<tr>
<td>Perforating arteries</td>
<td>Arise from internal thoracic artery in 2nd, 3rd and 4th spaces</td>
<td>They are large enough to supply the mammary gland</td>
</tr>
<tr>
<td>Superior epigastric artery</td>
<td>Terminal branch of internal thoracic artery. Enters the rectus sheath and ends by anastomosing with inferior epigastric artery, a branch of external iliac artery</td>
<td>Supplies the aponeuroses which form the rectus sheathing, including the rectus abdominis.</td>
</tr>
<tr>
<td>Musculophrenic artery</td>
<td>This is also the terminal branch of internal thoracic artery. Ends by giving 2 anterior intercostal arteries in 7–9 intercostal spaces and by supplying the thoraco-abdominal diaphragm</td>
<td>Supplies the muscles of anterior parts of 7–9 intercostal spaces, and the muscle fibres of the thoracoabdominal diaphragm</td>
</tr>
<tr>
<td>ASCENDING AORTA Artery</td>
<td>Arises from the upper end of left ventricle. It is about 5 cm long and is enclosed in the pericardium. It runs upwards, forwards and to the right and continues as the arch of aorta at the sternal end of upper border of 2nd right costal cartilage. At the root of aorta, there are three dilatations of the vessel wall called the aortic sinuses. These are anterior, left posterior and right posterior</td>
<td>Supplies the heart musculature with the help of right coronary and left coronary arteries, described later.</td>
</tr>
<tr>
<td>ARCH OF AORTA Artery</td>
<td>It begins behind the upper border of 2nd right sterno-chondral joint. Runs upwards, backwards and to left across the left side of bifurcation of trachea. Then it passes behind the left bronchus and on the left side of body of T4 vertebra by becoming continuous with the descending thoracic aorta</td>
<td>Through its three branches, namely brachiocephalic, left common carotid and left subclavian arteries, arch of aorta supplies part of brain, head, neck and upper limb</td>
</tr>
<tr>
<td>Brachiocephalic artery</td>
<td>1st branch of arch of aorta. Runs upwards and soon divides into right common carotid and right subclavian arteries</td>
<td>Through these two branches, part of the right half of brain, head, and neck are supplied. The distribution of two branches on right side is same as on the left side</td>
</tr>
<tr>
<td>Left common carotid artery</td>
<td>It runs upwards on the left side of trachea and at upper border of thyroid cartilage. The artery ends by dividing into internal carotid and external carotid arteries</td>
<td>The two branches supply brain, structures in the head and neck</td>
</tr>
<tr>
<td>Left subclavian artery</td>
<td>It is the last branch of arch of aorta. Runs to left in the root of neck behind scalenus anterior muscle, then on the upper surface of 1st rib. At the outer border of 1st rib, it continues as the axillary artery</td>
<td>Gives branches which supply part of brain, part of thyroid gland, muscles around scapula, 1st and 2nd posterior intercostal spaces</td>
</tr>
<tr>
<td>DESCENDING THORACIC AORTA</td>
<td>Begins on the left side of the lower border of body of T4 vertebra. Descends with inclination to right and ends at the lower border of T12 vertebra by continuing as abdominal aorta</td>
<td>3–11 posterior intercostal spaces, subcostal area, lung tissue, oesophagus, pericardium, mediastinum and diaphragm</td>
</tr>
</tbody>
</table>

Contd...
Thorax

Section 2

3–11 posterior intercostal arteries of both right and left sides arise from the descending thoracic aorta. Right branches are little longer than the left. Each intercostal artery and its collateral branch end by anastomosing with the two anterior intercostal arteries.

Bronchial arteries
Two left bronchial arteries arise from descending aorta. Bronchial tree

Oesophageal branches
2–3 oesophageal branches arise from descending aorta. Supply the oesophagus

Pericardial branches
Branches of descending aorta, run on the pericardium. Fibrous and parietal layer of serous pericardia

Mediastinal branches
Arise from descending aorta. Supply lymph nodes and fat in posterior mediastinum

Superior phrenic arteries
Two branches of descending aorta. End in the superior surface of diaphragm. These arteries anastomose with branches of musculophrenic and pericardiacophrenic arteries. Supply the thoracoabdominal diaphragm

</table>

in adults. Manubrium is subcutaneous and easily approachable (see Fig. 13.14). Bone marrow studies are done for various haematological disorders. Another site is the iliac crest; which is the preferred site in children.

Posture of a patient with respiratory difficulty: Such a patient finds comfort while sitting, as diaphragm is lowest in this position. In lying position, the diaphragm is highest, and patient is very uncomfortable (see Fig. 13.32).

In standing position, the diaphragm level is midway, but the patient is too sick to stand.

Patient also fixes the arms by holding the arms of a chair, so that serratus anterior and pectoralis major can move the ribs and help in respiration.

Paracentesis thoracis or pleural tapping: Aspiration of any fluid from the pleural cavity is called paracentesis thoracis. It is usually done in the eighth intercostal space in midaxillary line. The needle is passed through lower part of space to avoid injury to the principal neurovascular bundle (see Fig. 15.9).

Some clinical conditions associated with the pleura are as follows:

Pleurisy: This is inflammation of the pleura. It may be dry, but often it is accompanied by collection of
fluid in the pleural cavity. The condition is called the pleural effusion.

- **Pneumothorax**: Presence of air in the pleural cavity.
- **Haemothorax**: Presence of blood in the pleural cavity.
- **Hydropneumothorax**: Presence of both fluid and air in the pleural cavity.
- **Empyema**: Presence of pus in the pleural cavity.

**Coronary artery**: Thrombosis of a coronary artery is a common cause of sudden death in persons past middle age. This is due to myocardial infarction and ventricular fibrillation.

Incomplete obstruction, usually due to spasm of the coronary artery causes angina pectoris, which is associated with agonising pain in the precordial region and down the medial side of the left arm and forearm.

Coronary angiography determines the site(s) of narrowing or occlusion of the coronary arteries or their branches.

Angioplasty helps in removal of small blockage. It is done using small stent or small inflated balloon (see Fig. 18.27).

If there are large segments or multiple sites of blockage, coronary bypass is done using either great saphenous vein or internal thoracic artery as graft(s) (see Fig. 18.28).

Cardiac pain is an ischaemic pain caused by incomplete obstruction of a coronary artery.

Viscera usually have low amount of sensory output, whereas skin is an area of high amount of sensory output. So pain arising from low sensory output area is projected as coming from high sensory output area.

Axons of pain fibres conveyed by the sensory sympathetic cardiac nerves reach T1 to T5 segments of spinal cord mostly through the dorsal root ganglia of the left side. Since these dorsal root ganglia also receive sensory impulses from the medial side of arm, forearm and upper part of front of chest, the pain gets referred to these areas as depicted in Fig. 18.26.

Though the pain is usually referred to the left side, it may even be referred to right arm, jaw, epigastrium or back.

**Oesophageal varices**: In portal hypertension, the communications between the portal and systemic veins draining the lower end of the oesophagus dilate. These dilatations are called oesophageal varices (see Fig. 20.8). Rupture of these varices can cause serious haematemesisis or vomiting of blood. The oesophageal varices can be visualised radiographically by barium swallow; they produce worm-like shadows.

**Barium swallow**: Left atrial enlargement as in mitral stenosis can also be visualised by barium swallow. The enlarged atrium causes a shallow depression on the front of the oesophagus. Barium swallow also helps in the diagnosis of oesophageal strictures, carcinoma and achalasia cardia (Fig. 21.13).

**Coarctation of the aorta**: Coarctation of the aorta is a localised narrowing of the aorta opposite to or just beyond the attachment of the ductus arteriosus. An extensive collateral circulation develops between the branches of the subclavian arteries and those of the descending aorta. These include the anastomoses between the anterior and posterior intercostal arteries. These arteries enlarge greatly and produce a characteristic notching on the ribs (see Fig. 19.9b).

**Aortic aneurysm**: Aortic aneurysm is a localised dilatation of the aorta which may press upon the surrounding structures and cause the mediastinal syndrome (see Fig. 19.11).
A. Match the following on the left side with their appropriate answers on the right side.

1. Arteries and their branches:
   a. Internal thoracic
   b. Descending aorta
   c. Right coronary
   d. Left coronary
   i. Posterior interventricular
   ii. Posterior intercostal
   iii. Anterior interventricular
   iv. Anterior intercostal

2. Ribs:
   a. True ribs
   b. Atypical ribs
   c. Least fractured ribs
   d. Vertebrochondral ribs
   i. 8th, 9th and 10th
   ii. 1st, 11th, 12th
   iii. 1st–7th
   iv. 1st, 2nd, 10th, 12th

3. Vertebral levels:
   a. Aortic opening
   b. Oesophageal opening
   c. Inferior vena cava
   d. Gastro-oesophageal junction
   i. T8
   ii. T10
   iii. T11
   iv. T12

4. Mediastinum:
   a. Anterior mediastinum
   b. Middle mediastinum
   c. Posterior mediastinum
   d. Superior mediastinum
   i. Trachea
   ii. Azygos vein
   iii. Heart
   iv. Sternotericardial ligaments

B. For each of the incomplete statements or questions below, one or more answers given is/are correct. Select.

A. If only a, b and c are correct
B. If only a and c are correct
C. If only b and d are correct
D. If only d is correct
E. If all are correct

1. The apex of the heart:
   a. is formed only by left ventricle
   b. is situated in the left 5th intercostal space
   c. is just medial to midclavicular line
   d. is directed downwards, backwards and to the left

2. The aortic opening in the diaphragm:
   a. lies at the lower border of 12th thoracic vertebra
   b. transmits aorta, thoracic duct and azygos vein
   c. lies in the central tendinous part of the diaphragm
   d. is quadrangular in shape

3. The trachea:
   a. extends in cadaver from C6 to T4.
   b. deviates to the right at its termination
   c. is lined by ciliated pseudostratified epithelium
   d. is seen as a vertical radio-opaque shadow in radiograph.

4. Thoracic duct:
   a. begins at the lower border of L1
   b. is the upward continuation of cisterna chyli
   c. enters the thorax through vena caval opening in the diaphragm
   d. ends by opening at the junction of left subclavian and left internal jugular veins

5. Bronchopulmonary segment:
   a. is aerated by a segmental bronchus
   b. is pyramidal in shape with its base directed towards periphery
   c. is an independent respiratory unit
   d. is supplied by its own separate branch of pulmonary artery and vein

6. Visceral pleura:
   a. is pain insensitive
   b. develops from splanchnopleural mesoderm
   c. covers all the surfaces of the lung including fissures but not the hilum
   d. is innervated by autonomic nerves

Answers

A. 1. a – iv, b – ii, c – i, d – iii, 2. a – iii, b – iv, c – ii, d – i
   3. a – iv, b – ii, c – i, d – iii
1. a. Identify the part of the bone.  
b. Name the structures related to it.

6. a. Identify the structure.  
b. Name its main branches.

2. a. Name the joint shown.  
b. Name its type.

7. a. Identify the part.  
b. Name its segments.

3. a. Identify the part shown.  
b. Name the structures present.

8. a. Name the structure.  
b. Name its three openings.

4. a. Identify the part shown.  
b. Name its three branches.

9. a. Identify the part.  
b. Name its boundaries.

5. a. Identify the sulcus.  
b. Name the structures present.

10. a. Identify the ganglion.  
b. Name the connections with the ventral ramus.
1. a. Neck of 1st rib
   b. • Sympathetic trunk
      • Posterior intercostal vein
      • Superior intercostal artery
      • Ventral ramus of Th1 nerve

2. a. Manubriosternal joint
    b. Secondary cartilaginous joint

3. a. Hilum of right lung
    b. • Eparterial bronchus
       • Pulmonary artery
       • Hyparterial bronchus
       • Upper and lower pulmonary veins

4. a. Arch of aorta
    b. • Brachiocephalic trunk
       • Left common carotid artery
       • Left subclavian artery

5. a. Anterior interventricular sulcus
    b. • Anterior interventricular branch of left coronary artery
       • Great cardiac vein

6. a. Right coronary artery
    b. • Marginal artery
       • Posterior interventricular branch
       • Branch to SA node, AV node

7. a. Upper lobar segment
    b. 1 Apical
       2 Posterior
       3 Anterior

8. a. Thoracoabdominal diaphragm
    b. • Aortic opening
       • Vena caval opening
       • Oesophageal opening

9. a. Oblique sinus of pericardium
    b. • Inferior vena cava—below and to right
       • Pulmonary veins—above and to left
       • Left atrium—antero
       • Fibrous pericardium and oesophagus—posterior

10. a. Sympathetic ganglion
     b. • Grey ramus communicans
        • White ramus communicans

BD Chaurasia's
Human Anatomy

Regional and Applied Dissection and Clinical

Widely acclaimed as a standard text in view of its simple language, comprehensive coverage and attractive presentation, BD Chaurasia's Human Anatomy remains an ideal and the most preferred textbook in India and abroad. This edition of the book has been thoroughly revised, enlarged and updated, to make it still more student-friendly.

The eighth edition now features:
- Some newly drawn colour diagrams from the first edition matching with the latest diagrams
- Enhanced and well illustrated clinical anatomy given along with each concerned topic to increase the book’s utility to the student during the clinical years
- Volume 3 presents reinforced material on Head and Neck including a brief description of cranial nerves
- Volume 4 now highlights Brain and Neuroanatomy with MRI matching the diagrams
- A CBSiCentral App containing respective videos on osteology and soft parts for better orientation of these topics and FAQs with answers and diagrams for proper preparation for the examinations, accessible for each volume
- Some new chapters added to lend flavour to learning anatomy with enhanced interest.

This volume has • 50 tables • 504 figures • 6 flowcharts • 354 pages

Salient features of the four volumes

- The eighth edition has been designed as per the latest MCI syllabus featuring the text and headings following the “Competency based Undergraduate Curriculum for the Indian Medical Graduate, 2018”, prescribed by Medical Council of India.
- An attempt has been made to introduce “molecular regulation of development” of some organs in the book which will help in better understanding of the interesting aspect of embryology.
- Some select references have been given at the end of the chapters to enhance the horizon of students who need to read further on the topics of their interest.
- Actual dissection photographs have also been added to make the subject more visual and interesting.
- Many viva voce questions have been added which would definitely be of immense value to the readers. These questions would also help the students in their PG entrance examinations and in the interviews for getting the appropriate jobs.

Chief Editor

Krishna Garg MBBS, MS, PhD, FAMS, FAMS, FAMS, FASI is ex-Professor and Head, Department of Anatomy, Lady Hardinge Medical College (LHMC), New Delhi. She joined LHMC in 1964 where she completed her MS and PhD, and taught anatomy till 1996. She has received fellowships of the Indian Medical Association, Academy of Medical Specialists, and the International Medical Science Academy. She was elected fellow of the Academy of Medical Sciences (FAMS) in 2005. She was honoured with Excellence Award in Anatomy in 2004 by Delhi Medical Association. She has received Life Time Achievement Award, Fellowship of Anatomical Society of India, and DMA Distinguished Services Award, in 2015. She is visiting faculty of DNB, MDS and a PhD examiner.

She is author of Companion Pocketbook—BD Human Anatomy (Vols 1–3) and BD Human Anatomy for Dental Students 3/e; coauthor of Textbook of Histology 5/e, Textbook of Neuroanatomy 6/e, Anatomy and Physiology for Nurses, Anatomy and Physiology for Allied Health Sciences, Practical Anatomy Workbook, Practical Histology Workbook and Practical Anatomy Workbook for Dental Students; and editor of Human Embryology 2/e and Handbook of General Anatomy 6/e. Another book she has written is Anatomy and Physiology for Diploma in Pharmacy Students.

Editors

PS Mittal MBBS, MS is Associate Professor, Department of Anatomy, Government Institute of Medical Sciences, Greater Noida, UP

Mrudula Chandrupatla MBBS, MD is Professor and Head, Department of Anatomy, Apollo Institute of Medical Sciences, Hyderabad, Telangana.
